# Fertilization in Confinement.

G. W. DEMAREE.

I have been something of an enthusiast on the subject of controlling the fertilization of queens. I have felt sure fertilization of queens. I have felt sure that after so much has been accomplished in the way of reducing bee-culture to a respectable science, the good work would go on till the much-desired secret of successful fertilization in confinement would be discovered. With this hopeful state of mind, I determined not to be an idle spectator while others were prosecuting the work. In the month of August last I made what I called a fertilizing cage, provided with a steep glass roof. Thus prepared, I watched for a virgin queen, and when she came out to take her bridal trip I captured her and placed her in the cage,

watched for a virgin queen, and when she came out to take her bridal trip I captured her and placed her in the cage, which was set on top of the hive.

First one drone and then another, till a half dozen or more were put into the cage. The queen appeared to take her confinement quietly; inflated to the fullest extent, she showed her beauty to the best advantage. If you would see a virgin queen in all her glory, you must look at her when out on her heyday spree. The queen and drones flew lively in the cage, but the latter would do nothing but beat their cowardly heads against the glass roof, unconscious of the presence of the queen. After well-nigh baking myself in the hot sun, I gave it up and returned the queen to her hive.

SECOND EXPERIMENT AND FALLURE.

SECOND EXPERIMENT AND FAILURE.

The next day I proceeded to try the following experiment in hopes of throwing some light on the subject. I procured a pole 16 feet long, to one end of which I nailed a strip of wood about 4 feet in length, at right angles with the pole. Armed with a fine thread 4 or 5 feet long I watched for the queen, and when she came out I caught her, and by the aid of the deft fingers of Mrs. D., one end of the thread was made to

span the delicate waist of her royal highness, the loop being provided with a knot to prevent it from cramping her a knot to prevent it from cramping her waist—a performance, by the way, that required no little skill. Thus cabled, her wings and limbs were left free from incumbrance. The thread was now tied to the end of the transverse bar aforesaid, and the pole hoisted a few rods from the apiary. The queen performed nicely at the end of the thread. There were plenty of drones flying, and soon (I should think in 2 minutes' time) the air was black with drones circling about the fettered queen. Now and then one of them would give her chase, but when the thread would bring her to a sudden halt, he would dart to one side and disappear. Several times a drone struck her with considerable force, but would bound away as though suddenly frightened. I walched the proceedings closely bound away as though suddenly fright-ened. I watched the proceedings closely till the queen became weary and the drones retired. The experiment proved a failure as to the fertilization of the queen, which I attributed to the fact that the queen was somewhat injured by catching hold of a tuft of grass when the note was heing elevated. the pole was being elevated.

# WHAT THE EXPERIMENT SUGGESTED.

It is evident from what I saw in connection with this experiment, that a great number of drones follow the queen great number of drones follow the queen when flirting through the air, while out on her key-day spree, and perhaps the swiftest cavalier of them all overtakes and is accepted by her. Thus it would appear that nature in this way selects the swiftest specimens of the race to propagate the species. If this is not mere "theory," it goes very far to show why nature has provided so many males in commarison, with the number of dein comparison with the number of developed females, and why the latter must take the risk of fertilization in the

I gave much time last season to the I gave much time last season to the study of this subject, and I find that a well-developed virgin queen plies her wings with lightning velocity, and flies with wonderful rapidity. Now, if she does not give chase to the drones, how are we to account for the fact that she usually makes three or more tring into are we to account for the fact that she usually makes three or more trips into the air when drones are plenty? I saw one beautiful, slender little princess make 16 trips before she was caught by a drone. When she returned for the last time—having been gone 22 minutes—she fell short of the entrance of the hive, like a worker bee over-loaded with honey and pollen. Three days later she was laying.

was laying.

If nature has determined that the "race is to the swift" as pertains to the propagation of the honey bee, then perhaps nature will forbid the interference of the wisdom of man in this matter— or, in other words, fertilization in confinement will never be a success. Christiansburg, Ky., Nov., 1880.

For the American Bee Journal.

# My Bee Report for 1880.

of extracted honey, from unfinished sections. None but 15 cases of the comb honey is sold, and that here at home at sections. Notice that Backers of the comboney is sold, and that here at home at 15c, per lb., as it was the "culls"—i.c., combs hardly fit to ship, but a little too good to extract—such combs as were full of honey, but not all capped over. The 15 cases brought \$43,50. We will put the 93 first class at 20c, net (we feel sure we shall get it, for some of this apiary's honey is now sold so that our net receipt is 23c, per lb., all in the spruce figured sections), which will amount to 2,232 lbs., at 20c., will bring \$446.40. We will put the \$00 lbs. extracted at 10c, per lb. net, which makes \$80; honey sold at the apiary and brought home, say \$5.00; total receipts, \$574.90. The small increase will, in value, no more than offset winter losses perhaps. perhaps.

# Now for the expense account:

Hired help. Railroad fare and freights, say. 100 glassed cases for comp honey. 1,300 sections. Foundation for same.	15 10	$00 \\ 00 \\ 00 \\ 40 \\ 40$
This deducted from the income	\$227 574	S0 90
Leuves a net of	\$347	10
The investment is about as follow	TT C! .	

The investment is about as follows 

Some may think that the capital in-Some may think that the capital invested need not be so great, but I cannot see how I can get along with less and "do what is worth doing, well," unless, perhaps, about \$300 might be deducted for a dwelling house that we do not need or use very much, having two other capacious buildings.

The foregoing is a better result than The foregoing is a better result man I had supposed the figures would show, inasmuch as the *pro rata* yield is only about 16 lbs. of comb honey (counting 2 lbs. of extracted honey as 1 of comb).

My home apiary, of about the same number of colonies and investment, did about as well this season, for the first about as well this season, for the first time since the other was established. I find that well-bred stock, and well-kept apiaries, buildings and tools, pay the best interest on investment, either in good or poor seasons. If we have a "shower" of honey, we mean to be ready for every drop of surplus; if only a few drops, we mean to make sure of that. By the way, I came near forgetting \$50 worth of feed, fed in the Glenwood apiary, to make up the little that some colonies lacked. This reduces my pay for superintending to \$57.10; however, my hands there spent far more time here than I did there. The above is probably very close to the final results, when all is closed up for 1880.

Dowagiac, Mich., Nov. 11, 1880.

# Alsike Clover for Bee Pasturage.

M. M. BALDRIDGE.

Alsike or Swedish clover (*Trifolium hybridum*) as its name indicates, is a nahybritian) as its name influences, as a me-tive of Sweden, where it grows wild— being both hardy and productive. It is commonly known by the name of Alsike, commonly known by the name of Alsike, that being a parish in Sweden where this clover originated. It was brought into cultivation in Sweden about the beginning of the present century, was introduced into England in 1834, and soon thereafter found its way into the German States and other parts of Europe, and was finally brought into the United States, through the Patent Office, about the year 1853. the year 1853.

Alsike clover is regarded by botanists

Asike clover is regarded by botanists as a hybrid between our common red and white clovers. The stem and branches are finer and less woody than the common red, and when cut and cured for hay, it is perfectly free from fuzz or dust. It does not turn black, but remains the color of well-cured timothy. It has, as the following cut shows, numerous branches and a multitude of blossoms which are rich in honey. The blossoms which are rich in honey.

FIG. 1 .- Alsike Clover Plant in ble

bees have no trouble in finding the honey, as the blossoms are short and the heads no larger than white clover. The blossoms at first are white, but soon change to a beautiful pink, and emit considerable fragrance. The leaves are oval, of a pale green color, and may readily be distinguished at any stage of their growth from the white or red clover by the total absence of a pale white blossom on the upper surface of each leaf, a peculiarity unnoticed by previous writers.

It ripens, in the latitude of Chicago, in the latter part of July, but needs not to

the latter part of July, but needs not to be ent till August, if the weather should be unfavorable. The crop of seed is always obtained from this cutting, in which respect it is unlike the common wall. It is not advisable to cut this clother. which respect it is unlike the common red. It is not advisable to cut this clo-ver more than once each season, but it may be pastured moderately during the fall. When cut for seed, it may be threshed from the field with a common clover machine; but, if more conven-ient, it may be stacked and threshed during the fall or winter.

Care should be taken in handling this clover, as the seed shells very easily; but this is looked upon as a point in its favor, as the land thus becomes reseeded every year, and so early, that if the autumn proyes to be a wet one, nearly every grain will germinate, and a fine growth of new plants will be segured for the following year. The seed a me grown of new pants will be secured for the following year. The seed is very fine—being about the size and shape of white clover—a pound containing, it is said, about 600,000 grains, or three times as many as the common red. The seed-pods contain 1, 2, 3 and some-times 4 grains, which explains why it is

The seed-pools contain 1.2. 3 and some-times 4 grains, which explains why it is so prolific—a moderate yield being from 150 to 200 lbs, of seed to the acre. When sowed by itself, 4 lbs, of seed is a great plenty for an acre; but this is not the best plan to pursue, especially with our dry western prairies. It is much the better way to mix Alsike with timothy or the common red, or with both. When thus mixed, they are a help to each other. The Alsike being a na-tive of a cold climate, does not winter-kill, and besides, it acts as a mulch in winter and spring to the common red, and keeps the latter from being de-stroyed by the heaving-out process. As the red clover shades the roots of the Alsike, which grow close to the surface, it protects the latter from the effects of drouth. The timothy and red clover being both upright growers, lift and drouth. The timothy and red clover being both upright growers, lift and keep up the Alsike from the ground, which is very desirable. The stem of the Alsike is too fine to support its many branches in an upright position, and hence is more inclined to lodge than the common red. For the reasons given, the combination of the three named plants

ter, as an examination of figures 2 and 3 will show. Having often dug up specimen roots of both Alsike and the common red clovers for comparison and

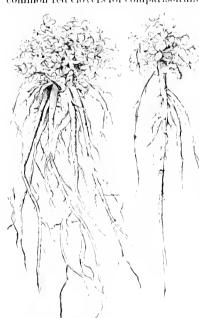

Fig. 2. Alsike Clover Root and Fig. 3. - Red Clover Crown, average size, one year Root and Crown, one year old.

exhibition, fully as much difference exhibition, fully as much difference in the size of the crowns and the quantity of roots and rootlets have been found as the cuts indicate. The representa-tions are very accurate, and the reader will do well to examine them closely and note the difference, which seems to be decidedly in favor of the Alsike. Having now grown Alsike on a variety of soils for the past 12 years with good success. I know that what I have set

But the main object of this article is to call special attention of bee-keepers to Alsike as a honey plant. It is well known to the fraternity that noy favorite honey plant is Melilot clover, than which none better has yet been found in the United States. But Melilot will never be cultivated to any extent except by bee-keepers, as no farmer would think of such a thing as growing it for hay and pasture. But Alsike clover is a plant that every farmer can and should cultivate, whether he keeps bees or not, as it is superior to the common red, for hay or pasture, for all kinds of stock. But the main object of this article is

Now, let me indicate to bee-keepers what should be done, and that right speedily. Suppose you have 50 or 100 colonies of bees, more or less, then visit the farmers in close range and ascertain how many acres they intend to seed down to grass the following spring, and induce enough of them to sow at least induce enough of them to sow at least as many acres to Alsike, timothy and red clover, as you have colonies. The more land you can thus get seeded down the better. Induce them, if possible, to buy the seed at the cost price, but if you cannot do this, let them have it at half the cost price, but if this fails, then make them a make them a present of as many nounds. make them a present of as many pounds as they will sow acres. They certainly could not and would not object to this last proposition, as it would be no more work to sow the grass seed mixed with Alsike than if it were left out. As the Alsike seed can now be purchased for about \$25 to \$30 per 100 lbs., instead of \$75 to \$100, the price when first brought here a heer range can now be simplied. combination of the three maned plants is very important, and will prove successful wherever tried.

When mixed, sow the usual quantity of timothy and red clover, and not more than 2 lbs. of Alsike seed to the acre—in fact, 1 lb. will be ample. If wanted for seed, it might then be best to use 2 lbs. of Alsike to the acre. Timothy and red clover do no harm, as the crop may be cut so early that the Alsike will be the only plant ripe enough to furnish seed. Timothy seed being about the same size of the Alsike, cannot very well be separated from it; but such is not the case with red clover, as a fine sieve will quickly do the work.

Alsike clover, as a fertilizer, must be as good a plant as red clover, if not better, as an examination of figures 2 and 2 will chorn. Having often during the control of the choicest honey every cause the bee-keeper to swin the present winter, hundreds the timest honey will be added the project; if so, I shall for repaid.

St. Charles, Ill., Dec., 1880. bere, a bee-range can now be supplied with one of the very best honey plants at a triffing expense. One hundred acres of Alsike, mixed with other grasses, in full bloom during June and July, in the neighborhood of 100 colories of bass would insure a large error. onies of bees, would insure a large crop of the choicest honey every year, and cause the bee-keeper to swing his hat with joy. Now, if every reader of the BEE JOURNAL will act upon this advice the present winter, hundreds of tons of the tinest honey will be added to the crop of 1882, and I am quite sure you will thank me for calling your attention to the project; if so, I shall feel amply

For the American Bee Journal.

# Wired Comb Foundation.

D. S. GIVEN.

The brood is reported as dying over the wires, and the queen skipping the cell over the wires, and some have seen the bees trying to remove the wires, and these statements have come from those whose word 1 cannot doubt. To say different bees treat it differently would be nonsense. Wired frames have been my hobby for the past 3 years.

Although wired foundation was given Atthough when conduction was given through Gleanings as an invention of it editor, a description of it can be seen 2 months before in the American Bee Journal, overmy signature. Though Journal, over my signature. Though this is an invention I am proud of, I canthis is an invention I am proud of 1.1 cam-not raise my voice with this scend in-ventor, against all these, and say "you most assuredly are mistaken if you mean to say our time tinned wire kills larva." I am frank to say my experi-ence has been much the same as others have reported. In the spring of 1878 I had to pull the wires out of 200 frames, just as that British cousin had to do, and found it a bad job. But I changed my wire and found it better, and have observed that in the cells which failed, the wires crossed the cells and were not adwires crossed the cells and were not adhered to the septum. After a while I found, by giving it much time, I could obtain a perfect frame of brood, on the plan I gave in the BEE JOURNAL for July, 1878.

plan 1 gave in the BEE JOURNAL for July, 1878.

Since that time all my frames have been wired. The points I noted were these: The wire must be fine timed wire; the wire must run the way the line runs in the foundation, and be placed along the line of cells and well pressed into the flat side of the septum. Those who will take all this care, can have every cell laid in, and the eggs warms can generally be prevented, ancented. It was the trouble to do all

forth in this article are facts and not this that induced me to invent the press and those that are weak can be strengththis that induced me to invent the press to put it all there at one impression, and I believe no one has complained of the brood dying, or being skipped by the queen, where the frame was filled on the press. If so, I would be glad if they would speak ont.

All foundation in the wired frame has the center of the comb in the center of the frame, whether the frame hangs exactly perpendicular or not. The wired frame was invented to avoid sagging; it will not only do this, but I am more than paid for all extra expense by the

than paid for all extra expense by the nice straight combs, that do not break

in handling or in transit, or by sitting in the sun; and where the extractor is used, only those who have used the wired frame can appreciate the great advantage of it.

Hoopeston, Ill., Nov. 18, 1880,

# Adulteration of Syrups, etc.

S. K. MARSH.

Last year I had 4 samples of syrups analyzed by Prof. R. F. Kedzie, at the laboratory of the Agricultural College of this State. The syrups cost, respectively, 54c., 60c., 65c. and 80c. per gallon, the average price being 65c. per gallon. I requested him to compare the price of the actual sweet the syrups contained actual sweet the syrups contained with extracted honey, at 10c, per lb., and here is the result:

No.	1.+65c,	per ga	130.91	per cent.	glucose	sugar.
**	254c.		39.01		**	**
**	3S0c.	**	35.56	**	**	**
••	4,-60c,		33.44	**		**
	Avers	uze	34.73	**	* 1	• •

 $\Lambda$  gallon of syrup weighs about  $11^{1}_{\,2}$  lbs., and contains about 4 lbs. of glucose sugar on an average, and costs 1614c. per lb. of glucose sugar.

# BUT ONE PURE IN TWENTY-ONE.

Four analyses of honey gives an ave Four analyses of honey gives an average of \$3.01 per cent, of sugars, 2.01 per cent, of which is cane sugar, the remainder being grape sugar; 11½ lbs, of honey at 10c, per lb, costs \$1.15, and contains \$½ lbs, of sugars, which cost 12½ c, per lb, while the glucose sugar in syrups costs 16¼c, per lb. Of course, there is a great difference in syrups. Some, doubtless, are better than those I sent to Prof. Kedzie, while some, no sent to Prof. Kedzie, while some, no doubt, are poorer; but the following will give some idea what a small chance we have to get any pure cane syrup: Prof. Kedzie says: "During the past year I have examined 21 specimens of syrups. Of these only I was pure cane syrup, 2 were mixed cane and glucose sugars, and the rest were glucose sugar syrups.

# HONEY CHEAPER THAN MIXED SYRUP.

Some of my customers find fault with Some of my customers find fault with having to pay 10c, per lb. for honey, when they can buy syrups so much cheaper, but I am now prepared to show them that they pay much dearer for what little poor sweet they get in syrups

at the average price, than they do for the sweet they get in honey at 10c, per lb. Sugars are also being so badly adul-terated that this year I have made a little experiment in early amber sugar cane, and think I can raise 150 gallons of syrup to the acre. It fills the place of sugar

in nearly every place.
Palo, Mich., Nov. 4, 1880.

From the Canada Farmer

# To Beginners in Bee-Keeping.

CHAS. F. DODD.

Formerly bee-keeping was carried on with "box hives" or "log gums," the insides of which were a complete mys-tery. The bees were generally left to tery. The bees were generally left to themselves until the close of the honcy season, when they were brutally smoth-ered with brimstone, and the colony be-ing thus exterminated, its stores were

ened, by giving them comb, bees honey.

honey.

Bee-keeping well deserves a place among the industries of the farm. As it is wise to keep poultry to pick up the waste grain and stray seeds, so it is wise to keep bees to gather the nectar of clover, or chard blossoms and wild flowers that would otherwise go to waste.

ers that would otherwise go to waste.

The chief trouble with beginners is that they will not go to the slight expense and small trouble necessary to get information on the subject. They buy a hive of bees, about which they know nothing, except that bees can sting and nothing, except that bees can sting and that their honey is nice, and then leave it to take care of itself. It is needless to say that this is a very foolish course to adopt. What wonder that only failure and loss are the result; it would be the same in sheep-raising, dairying or any other line of farming. While, therefore, we advise the farmer to make beek leaving one of many lines of indusbee-keeping one of many lines of industrial pursuit, we qualify the advice by arging that it be by no means entered into without seeking information in regard to it.

# HONEY REPORT FOR CANADA.

Facts and figures from all parts of the country, indicate that the entire crop of honey for 1880 is but one-half of the usual supply. Nile, Ont.

For the American Ree Journal.

# Fertilization in Confinement.

This subject appears to be losing interest with prominent apiarists. It is a little surprising that so many experienced bee-keepers who have studied the liabits of the honey bee for years, and have tried this experiment, should promounce it a failure. It was by diligent study of the nature and liabits of the bee I made this important discovery. I have five queens fertilized in a cage made for the purpose. Every trial was a success: I found the dead drone on the bottom of the cage, each time. I returned the queen to the colony and all was right. These five queens are very prolific; their workers are large and landsome, giving entire satisfaction, thus far; what they will do in the future, remains to be seen. This subject appears to be losing in-

tion, thus far; what they will do in the future, remains to be seen.

This cage is more nearly adapted to their true natures than any other plan. I have seen described. The labor of the hive goes on unmolested, the bees passing out and in as before. No catching, contining or scaring of the queen; she acts upon her own impulses and at the proper time.

If any one has made further discoveries, I would be glad to have them report. Before the work of 1881 rolls round, I will give a full description of my cage and its use.

# Lower Ventilation in Winter.

WM. САИМ.

After our cold snap in November, I raised some of my hives and found an unusually large number of dead bees on the bottom boards and on the lower part the bottom boards and on the lower part of the combs and frames, also considerable ice on the stands. I am forced to think that one of the greatest points in wintering anywhere, or in any repository, is to keep the hives perfectly dry. I notice this winter that some of my hives that had 12x12 frames cut down to 10 in. deep, and hives left unchanged, so that there is a space of 25g inches be-tween the bottom board and bottom bar of frames show no ice, and few dead bees, though the hives are no better con-structed or sheltered than others where-

structed or sheltered than others wherein there is such a great mortality.

1 am at a loss to account for the
recommendations of Shuck and others,
who are presumed to have experience,
to have a hole in the bottom board 6
inches square, covered with wire-cloth,
for the purpose of lower ventilation. I
tried this in my earliest experiments,
and have one such hive left yet, but it
was a complete failure for though there was a complete failure, for though there was a slide underneath to darken the

aperture, open or shut the bees scaled up every mesh in the wire-cloth. Nor have I been able to cover my bees with anything that they would not ename! with propolis, unless it was already enameled.

enameled.

The double-width hive, with division board and roof, or a set of Huber frames surrounded by an outer case, are the best "contraptions" I know of, and if these were kept under a shed so that in winter they could be covered with straw, and the straw kept dry, it would be the best we could do, and the easiest and cheapest way of doing it.

# How to Make and Feed Good Candy.

F. C. BENEDICT.

As winter is upon us so early and so As winter is upon us so early and so severe. It fear many of our little pets will want for stores before next May, and some may be glad to know how to make candy that will be right, without any

guess-work.

Take coffee A sugar 4 lbs., water 1 lb. (add wheat or rye flour 1 lb., if you wish to stimulate brood-rearing), put in a pan over a moderate fire (being careful not over a moderate fire (heing careful not to scorch it), boil for 20 minutes; then place it in a pan of cold water or on snow; stir until quite stiff, which will make it fine grain; place in frames that will cover one-half the brood chamber, leaving a space under the candy so that the bees can get at the whole surface; place the blanket over the other half of the brood chamber and the chaff cushplace the blanket over the other half of the brood chamber, and the chaff cush-ion over the whole, and they are in fine shape. Moisture enough will gather on the candy that the bees can take it readily, and the balance will escape through the quilt and cushion. As this candy may be given any time during the winter, when the weather is mild, do not let your bees starve from ungled do not let your bees starve from neglect, nor poison them with grape sugar. Perry Center, N. Y., Dec. 13, 1880.

For the American Bee Journal.

# Bees Deserting Winter Quarters.

D. S. KALLEY.

Mr. Editor: Will you, or some of your readers, tell me what is the matter with my bees? I put 16 colonies into winter quarters on their summer stands, wrapped well in straw and chaff, on the 20th of October, and all through Novem-ber and until now (Dec. 8) they are coming out and flying away, leaving plenty of honey to winter on. Great numbers of koney to winter on. Great numbers come out on the platform after night and die by the handfull: four colonies and the by the handed it. I am perplexed over the matter. The coldest mornings we have had, they come out at daylight and fly away. Success to the BEE JOURNAL; I like it well.

Mansfield, Ind., Dec. S. 1880.

(Without knowing the exact manner and amount of packing, the appearance and condition of the combs and honey left in the hives, and peculiar motions of the bees on coming out, it is impossible to more than surmise or guess at the cause.—ED.]

From the Prairie Farmer.

# Honey-Wash for the Eyes.

WILL, M. KELLOGG.

Honey is an excellent remedy for inflammation of the eyes. In 1878 I was afflicted with inflammation of the right afflicted with inflammation of the right eye, which became very painful. Mr. C.O. Perrine, of Chicago, told me honey would care my eye. His method was to put a few drops of pure liquid honey into a teaspoonful of lukewarm water, and stir with the finger until thoroughly dissolved, then lie down and drop three or four drops into the eye, lying still a few minutes, then wiping the face and eyelids, but not washing out the eye. Repeat this 4 or 5 times a day, and the last thing before going to bed. I followed directions faithfully, got immediate relief, and in a few days the inflammation was entirely gone. was entirely gone. Oquawka, Ill.

# Letter Drawer.

Foul Brood.—In the proceedings of the Convention at Cincinnati, I see Mr. C. F. Muth gave his plan for treating foul brood, to which I can heartify sub-1 bought some old combs last scribe. scribe. I bought some our cours ast spring that bees had died on. The result was that I had one case of foul brood. I took a new hive and filled it with foundation and fed the bees with honey containing a little salicylic acid mixed with it. This fall it was as good nonley containing a fitter sandy is examined with it. This fall it was as good a colony as I had in the yard. Bees hardly made a living in the early part of the summer, but they did splendidly in the fall. I am well pleased to know we have weekly visits from the BEE hardy at Language II.

Journal. Long may it live.
L. A. Pennoyer.
Winona, Minn., Dec. 2, 1880.

Late Breeding. - 1 can remember no time where the season as they did this. As late as Oct. 10 they gathered honey with great profusion from asters, red and white clover. In the first week in October the bees gathered more honey then the reliable in the August Leonth. than they did during the August dronth, and by an examination, I also found that a majority of my colonies were then rearing brood to a great extent and in some cases the queen was then laying. Does this indicate a good winter for bees? The great progress now in beebees? The great progress now in beekeeping is not lacking here. Mr. E. Markel, an old bee-keeper of 15 years' experience, formerly used the common box-hive but now uses the Langstroth. with all other additional improvements in the apiary. He has partially Italianized his apiary. It is a great credit to him to bring such fine honey in 2-lb. sections to the LaCrosse market; the American Beejournalishis constant guide in the mangement of his apiary. I am glad that we are to have a Weekly paper during 1881. It has long been needed, and I hope all the old subscribers to the American Bee Journal will promptly renew their subscriptions, and thus show their appreciation of this "new departure" of the Editor.

L. H. PAMMEL, JR.

LaCrosse, Wis., Nov. 26, 1880. AMERICAN BEEJOURNAL is his constant

[This is a good idea; no one can show by promptly renewing their subscriptions for the Weekly for 1881,—Ep.]

Preparation for Winter.—I have just fractions of a dollar send one, two or finished putting my bees into winter quarters. They are nearly all in fine condition to go through the winter, having an abundance of male is the storing.—This season I have had condition to go through the winter, having an abundance of sealed honey and a fair amount of bees. I winter them under a shed, facing the east. I contract the brood-chamber, by use of division-boards, and then pack straw or leaves around them and on top. I think queens may be too prolific. Several of queens may be too prolific. Several of my hives were overflowing with bees of these are now poorer than others not having so many bees at that time. The having so many bees at that time. The abundance of bees consumed the spring supply of honey and were not able to gather any in the fall. I have recently traveled over parts of six counties of Ky., and find many colonies in a poor condition to stand a hard winter. Unless they are well cared for, and freely fed, many merry hives will be silent in death long before spring. When, Oh! when will formers give their bees the death long before spring. When, Oh! when will farmers give their bees the same care they do other stock on the L. Jounson. farm? Walton, Ky.

Report for 1880.-We started the season with 240 colonies in good condition. Our surplus boxes were put on early and Our surplus boxes were put on early and everything was done to secure a crop of honey that could be. During fruit bloom and white clover, bees gathered enough to keep even. On basswood they lilled their hives. Nights were cool all spring and summer till July, then we had warm nights when there was no bloom, cool nights all fall. Our surplus, therefore, from 246 colonies is 10 lbs, of honey and I swarm, and that 10 lbs, is honey-dew and not honey—the nectar of flowers. Of all conditions for

surplus honey, give us warm nights, for then the flowers secrete nectar. We obtained but little honey during a season when we had cool nights. There are, however, some good features about this bee business, when we have no honey crop, i.e. we have plenty of empty lives, sections, separators, foundation, glass, etc., to run us for many years to generally we did not be supported by the description of the bridge that carries me safely over."

Jos. 11. Fisher.

Napoleon, O., Nov. 17, 1880. glass, etc., to run us for many years to come if we do not use more than we did

during the last two seasons.

D. D. Palmer.
New Boston, Ill., Nov. 14, 1880.

Mustard Plant.—We cannot keep up with the times in keeping bees without the BEE JOURNAL. The honey season for ISSO was good in this locality. Can we get mustard to blossom by the 15th or 20th of June, if sown very early?
A. A. DECKER.

Granger, Wis., Nov. 19, 1880.

[Of course you can.—Ep.]

My Report.—I started last spring with 44 colonies and I have at present 51, nearly all in good condition for winter. My expenses were \$41.50 and my income is about \$22.00 for honey, and the increase of 10 colonies of bees. It was a poor year for bees here.

John Boerstler.

Batchtown, Ill., Nov. 21, 1880.

The Mitchell live.—Do not stop my JOURNAL if I should not get you the money by the first of January. Put me down for the Weekly JOURNAL for ISSI; I cannot do without it. My bees are packed for winter on the summer stands with 12 inches of straw around, except in front. I am using the Mitchell hive but have never yet paid \$5.00 for the privilege of using and do not expect to. I am glad at the prospect of getting the BEE JOURNAL every week.

CALVIN HOLLOWELL.

Dunreith, Ind., Nov. 23, 1880.

[Certainly: if requested to do so, we

(Certainly; if requested to do so, we will cheerfully send on the BEE JOUR-NAL and give a few month's time. We do not desire to be unaccomodatingbut cannot do a general credit business; still there are exceptions to all rules. It any one desires the Weekly Bee JOURNAL and it is not convenient to their appreciation in a better way than pay for a year at once, they can send \$1.00 for 6 months or 50 cents for 3 months. It costs no more in that way, except the trouble and postage. For all

> Side Storing.—This season I have had another chance to test the utility of side-storing. We had no honey until Aug. 20th, when we knew it was too late to get two crates of honey from any hive, but most of our colonies would more than fill one crate, hence I could not "tier up." Here is how they did it in those hives with 15 frames surrounding the broadnest they not only gave in those lives with 15 frames surrounding the brood-nest, they not only gave me one beautiful crate of honey. (35 lbs. net.) but did from \$5 to \$10 worth of work in the side chambers. None offered to swarm, while those in other hives took the swarming fever just in time to ruin any properts for honey. I have 40 colors my prospects for honey. I have 40 colonies in such hives, and would be surprised to find one dead next spring.

Well Pleased.—FRIEND I read everything I can get hold of per-taining to bees or bee men, and I deem taining to bees or bee men, and I deem you the most devoted and unselfish friend the bee-keepers now have. I am a stranger to you, though I have ever been your most sanguine friend since I first commenced taking the AMERICAN BEE JOURNAL, over two years ago. I was first induced to subscribe for the JOURNAL through Mr. D. Kepler, a neighbor and friend of mine, who was at that time your fast friend, and recom-

Caution to Dealers. - A little over two months ago I received my first lesson, and I think the last one while I am in the supply business. Mr. W. L. Woodand I think the last one while I am in the supply business. Mr. W. L. Woodward, formerly of Salford, Ont., wrote to me stating that he had gathered up for me 275 lbs. of beeswax. I offered him 28c, per lb., cash on delivery. He thought as we had dealings with each other the last 2 years, I ought to remit first, which I declined to do, as it would amount to \$77, we being strangers to each other personally. Finally, he said if I would remit \$28, he would forward the 275 lbs, of wax at onee on receipt of the money, at the same time stating that two other parties were after the that two other parties were after the wax, at the same offer. I remitted the \$28 in a registered letter, which he received, and that is the last of it, for he left for parts unknown, as I am informed by people in Salford.

M. Richardson.

Port Colborne, Ont., Nov., 1880.

[We publish the above, as a caution to supply dealers and others, at Mr. Richardson's request. We can sympathise with Mr. R., having had many similar experiences. One such swindler, after running into our debt, had the audacity to write thus to us: "Let me give you a piece of advice—never to trust strangers." What a pleasure it would be to do business, if all were honest. But there are black sheep in every flock; dishonest men in every community, and annoyances in every business.—Ed.1

Keeping Bees for Pleasure.—My bees (35 colonies) have done very poorly. I fed about half a barrel of sngar during the early part of the season. Bees gathered some honey late in the season, about 10 lbs. to the colony, and put it in combs built in 1879. My bees are in my winter repository, in fair condition. Bees are not my resource, but my pleas ure, so I am not as badly disappointed as some. My farm of 450 acres demands my attention sometimes when the bees need it, so I do not expect the largest results.

ALVAH REYNOLDS.
Oneida, Ill., Dec. 8, 1880. ceeping Bees for Pleasure.--My bees

Bees Starving.—I had to feed this fall: all the bees had was comb. I fed them coffee A sugar melted, and I think may coffee A sugar melted, and I think may get them through the winter safely. This was the worst honey year we have had for a long time. I think this winter will about clean all of the bees out of the old box hives, for I do not think there is any honey in them to winter on. We had lots of white clover, but the hees did not work on it the whole year. hees did not work on it the whole year, for some cause or other. I suppose there was no nectar, and it was so dry that bees obtained nothing from goldenrod; it just burned up, without blossoming out full, and I have had a siege of feeding. My bees will not pay expenses this year, but still I live in hopes of a good honey crop next year. Success to the weekly JOURNAL. I could not do without it for twice its cost.

R. L. AYLOR.

R. L. Aylor. Waterloo, Ky., Dec. 8, 1880.

Wintering Bees.—I had 20 colonies last spring, which wintered without loss; increased to 39; sold 800 lbs. of honey in 5-lb. boxes; each colony has on an average 50 lbs. of honey to winter on. I winter in a shed covered with hay, dug in the east side of a hill, 24 ft. long, 8 ft. wide and 6 ft. high, banked up on the north and south, and open on the east; the opening I fill in with hay in cold weather; it is dark and warm; in warm weather I remove the hay for the bees to have a fly without removing them. I have wintered twice in this way without loss.

# THOMAS C. NEWMAN,

EDITOR AND PROPRIETOR.

CHICAGO, H.L., JAN. 5, 1881.

# New Year's Greeting.

To-day The American Bee Jour-NAL presents itself in a new form—with open page and smiling face tendering its salutation to all its readers. The present form and style of page is the most convenient (all things considered) in which a periodical of its class could be presented; and it will doubtless be esteemed and admired.

The BEE JOURNAL enters upon the present year with a record of unparalleled success as an apicultural journalstarted as a monthly twenty grars ugo. to-day it blooms into a full-grown WEEKLY, with a promising future.

Its initial number, published in January, 1861, was the first publication ever issued in America "devoted exclusively to bee-culture," and now it is the only Weekly paper devoted to apiculture in the World!

THE AMERICAN BEE JOURNAL WAS called into being by the necessities of the times. It was designed to advocate the cause of progressive bee-keeping. To its mission it was ably and faithfully dedicated by its founder. To support its "high calling," we are fully determined to use every means within our power. Our watchword is "Progress," and our motto, "IMPROVEMENT.

We do not desire to boast, but we want every subscriber to feel that the money paid for it is but a tithe of its real and practical value in the manage ment of the apiary, and the production and sale of pure honey

Its old patrons, to whom it has long been a guiding-star, as well as its thousands of NEW readers, will together hail this issue of the BEE JOURNAL with joy. For many years its friends have desired more frequently to see its smiling face and read its refreshing articles. Now their dream of the future is to be realized, and we trust that neither the Journal nor its friends will ever have occasion to regret this "progressive step."

The BEE JOURNAL will take a lively interest in all wise efforts looking to the advancement of the art and science of bee-culture. We shall aim to give "all the news" respecting inventions and improvements in management, no matter where they may emanate-whether in the States, Territories or Provinces of America, or the countries of Europe, Asia or Australia. For some we may be too broad in our views, for others too narrow; to some we may seem too precise, to others too liberal: but no matter permit.

In giving our readers "the news" the der a new aspect.

One thing must not be forgotten—and the BEE JOURNAL points to it with pride—its contributors are among the most experienced and successful apicul- from one of the Chicago daily papers, turists in the world. We take this onportunity to express our thanks for their valuable communications, which have done much to develop progressive apiculture, and bring it up to its present standard of excellence.

As a weekly, it will review all the monthly magazines as they come out. giving each proper credit for all extracts and selections—the aim being not to ina beloing hand, whenever and wherever necessary. It will seek to act in harmony with all, and should it have cause to differ with any, it will do so with the best of feeling, and with convincing but kindest criticism.

Its interest in progressive bee-culture will cause it to labor for methodical work and organization; for these it will continue to exert itself with unabated zeal and devotion. Its influence will butter and 80 per cent, of fat mattercontinue to be felt for progression, both at home and abroad.

The many friends of the Bee Jour-NAL are invited to continue their cooperation and support, and assist in making the present volume even more valuable than any of its predecessors. To one and all we tender our compliments, and fervently wish each

# A HAPPY NEW YEAR.

A Christmas Present.-Now that the volume of the BEE JOURNAL for 1880 is complete, we find that we have a few complete sets of numbers, and shall immediately have them bound. As a volume of reference it will be very valuable to the beginner or the more advanced bee-keeper, and will be an excellent Christmas Present for a beekeeping friend. Price bound in paper covers, \$1.50, postage paid; in nice leather and cloth binding, \$2.00. Those who wish one, should order early as there are but a few of them to dispose

Pr. N. P. Allen, President of the National Association is contemplating a trip to Florida, Texas or California, to spend the winter. His object is to improve his health, and at the same time to assist in building up local associations and to further the cause of anicultural progression. President Allen has the reputation of being a good dentist, and will incidentally practice his calling to some extent in the places he may visit. Any one in these States interested in scientific apiculture is invited to correspond with him, in reference to his proposed trip. Should be carry out this programme, we hope he will spend a pleasant winter, recruit his health, and also render substantial assistance to the cause of apiculture.

Will it injure my bees to be covered up with snow?" This inquiry is whether praise or blame be heaped upon sent us by a correspondent. Certainly us or our efforts, we are fully determined not; and the more snow the better, to give as near "exact justice" to all providing it is dry snow. Sufficient as our capacity and knowledge will ventilation for the bees will pass through ordinary dry snow, but with the "wet" or "beavy" article it is another thing. BEE JOURNAL will not lose sight of the Care should be taken that the entrances fact that opinions and discussions them- do not become closed with ice, and to selves are "news," while presenting keep the hives on level or high ground, facts that are new, or even old ones un- to prevent them from being flooded when the thaw comes.

# Where are we Drifting?

The following advertisement we clip and is only one of several of a similar character which have from time to time appeared in the same sheet:

I WANT A MAN THAT IS POSTED IN MANUfacturing margarine or lard-butter, either salars or interest. Address T 95, Daily News. 379:26

Now, were a person to advertise for a confederate to assist in making counterfeit money or boons coin we doubt not detectives would work the case up and by skillful means soon arrest, conjure them, but to foster and lend them vict and imprison the proposed counterfeiter, as he would richly deserve. But as it is only a popular article of food to be counterfeited, it resolves itself into mercantile and manufacturing enterprise, and is "business." Suppose however, the advertiser finds his "man that is posted " (as undoubtedly he has). and they manufacture "margarine, "lard-butter," or, in plain English, bogus butter, using 20 per cent, of good rendered from cattle, hogs, horses, dogs, and other carcasses taken up from the streets, the stock yards, Bridgeport and elsewhere, and carried "just over the line into Indiana" for manufacture, and brought back to be sold as "pure leaf lard"—and one of our readers ignorantly buys this stuff for genuine butter, and innocently pays for it with counterfeit money (which is as genuine as the butter he buys), he will immediately be arrested, and the innocent butter-vender becomes the most indignant and clamorous prosecutor.

This matter of food adulteration is nothing new. The question no longer is "What is adulterated?" but "What is pure?" Tea, coffee, spices, bakingpowder, sugar, syrup, honey, flour, vingar, liquors, drugs, medicines, oilseverything, even butter and cheese But who is at fault for all this, except the apathetic public? For many years honest bee-keepers have suffered in two ways from the adulterous tendency of the times-first, from being brought into competition with glucosed sugars and syrups; and, second, from being obliged to sell in a market flooded or ruined with glucosed honey. True, in two or three States they have succeeded in getting well-meant but mistaken laws passed prohibiting the sale of mixed honey; but these were and still are inoperative dead-letters on the statute books. Nowhere have they received the support and co-operation of the masses of the people, and we have yet to hear of the first attempt at their enforcement.

Never has the subject of food adulteration received the attention it has urgently demanded, till now when the disgusting but most unhurtful side of the question has been presented. Glucose made from refuse corn was sold as pure sugar in every grocery in the land, and even the poisonous acids used in its manufacture scarcely provoked a remark; glucose syrups, as innocent of contact with sugar-cane as the butter and cheese of to-day are innocent of origin from the beastly cow, were temptingly poured as silver-drips over the warm cakes with which to poison our little ones. Candies, beautifully painted yellow, green and red, formed into attractive toys, lozenges and hearts. and inscribed with Christian mottoes and love-tokens, were made from terra alba (white earth) and glucose, with lbs, are given as the average.

which to plant the germs of Imgering disease in the new generation. Jellies. beautiful to behold, supposed to be made from the rarest and best fruits, were sold from grocers' counters at less prices than honest apple-parings could be purchased. Every bushel of corn, that in the days of our grandfathers would have made but a gallon and a half of honest whisky, now, by the use of poisonous acids and chemicals, will make several times that amount, and an hundred times the amount of delirium, pauperism and crime. Drugs and medicines, on the purity of which many lives are dependent, have been mercilessly adulterated, and the honest, time-honored and venerated physician, in his prescription not having kept pace with the latest adulteration, loses his patient and is berated for a want of medical skill.

We want no special or local laws to forbid and threaten to punish adulterations. The people will not be satisfied with a law which declares it a crime to make butter and cheese from the fatty portions of hogs, cattle or carrion, and leaves the inference to be drawn that it is honest to sell as pure and wholesome sugar and syrup made from glucose; we do not want a legislative enactment which makes it a misdemeanor to manufacture and sell as "strained honey" the product of anything but nectarvielding flowers, and leaves the matter to enterprise to make maple sugar and syrup from anything that can be flavored and colored. We do not want any law that will punish swindling, and fraud. and obtaining money under false pretenses in one locality, and to countenance the same in another. We do not want a law which is vindicated when the makers of bogus butter are punished, and allows all kinds of counterfeit and even poisonous food to be sold under every other name but the proper one.

We do want a law as general and comprehensive as the government itself, to punish all fraud in the sale of food; we want it as applicable in New York as in Chicago; as applicable in the West and South as in New England. We want a law as easy and certain of enforcement as any other police or sanitary regulation. We want a law which will guarantee to every purchaser that he is buying just what he calls and pays for. Each special law is a stumbling-block and hindrance in the way of a general law. Every local law makes general legislation more difficult to obtain, and but adds to the long array of inoperative enactments. If parties must make vile compounds, oblige them to be sold for just what they are. The time is in the near future when these laws will be irresistibly demanded of Congress, and until that time comes, the already overindulgent and heart-sick public must suffer and bear.

Bees in Kansas.-We have received the third quarterly report of the Kansas State Board of Agriculture. In it we find that only about one-third of the counties of the State report a fair erop of honey. Brown county has 198 colo nies of bees, which produced 6,983 lbs. of honey and 150 lbs, of wax. This is an excellent report, and "Brown" is evidently the banner county of the State for honey production. Doniphan county reports from 10 to 50 lbs, of honey for each colony. In another county 65

# Stingless Bees of South America.

In the report of the Southern California Bee-Keepers' Association, on page 6 of this JOURNAL, mention is made of an article from the New York Argus, on the "Stingless Honey Bee;" and we have a circular on our desk from Mr. Hawley, of Rochester, N. Y., advocating the formation of a "Stingless Bee Association." In it Mr. Hawley evidently refers to the article in the Argus, as its parent:

"On the 15th of September last the undersigned published in an Albany newspaper an article on the subject of 'Stingless Bees,' which, so far as 1 am aware, was the first intimation the bee fraternity of the United States had that there existed anywhere on the habitable globe a species of the honey bee that have no stingers ..... By accident the writer of this was first made acquainted with the fact that this singular species of bees existed; then history, travels, and personal inquiry, the fact was demonstrated and proven that the species really

existed.
"Then, by correspondence, these further facts were elicited: That these bees are indigenous to Brazil, south of the equator, inhabiting a climate similar to that of Italy, and with surroundings very like those of that country; that, with a single exception (where a French sailor, having some knowledge of bee-culture in France, had for a few years been conducting an apiary on a very primitive scale—his hives being cut from the forests with the bees already in, hauled and set them up at his cabin-and, to obtain the honey, he kills the bees and appropriates their stores; depending upon increasing his colonies by natural swarming), no one in the whole empire paid any attention to the cultivation of bees, and for this reason it would seem necessary, to order to introduce them here, that some competent person make the trip to South America and bring them here,'

Mr. Hawley is rather unfortunate in his statement that the publication of his article " was the first intimation the bee fraternity of the United States had that there existed anywhere on the habitable globe, a species of the honey bee that have no stingers." Evidently he has not read the American Bee Journal. or he might have seen in Vol. I., pages 234-5, published twenty years ago, a discussion concerning their utility. the close of this article, the late Mr. Samuel Wagner, our respected predecessor, made the following editorial comment:

"The Mexican and South American stingless bees might probably be made a source of profit in their native lati-tudes, if their instincts and habits were thoroughly studied and well understood. They are not suited to northern climates, and cannot be preserved here, as mere curiosities, without great care and difficulty.'

Page 54 of Vol. II., contains a descriptive article on bees and bee-keeping in Brazil. On pages 24, 25 and 26, Vol. IV., is a very interesting article on the habits of the Mexican bees. On page 179 of Vol. V we find a description of bees in Yucatan, concluding as follows: "They (the log hives) are well arranged under sheds erected for the purposeopened monthly and the honey extracted. They do not yield so much honey, or of so good a quality, neither are the bees as lively as those of the north. Their bees have no sting." The following is Mr. Wagner's editorial comment: "These bees are Meliponas, and might perhaps be cultivated in Florida, but all attempts to introduce them in the North have hitherto failed.'

Last year's volume of the Bee Jour-NAL contained an article on bee-keeping in Brazil by Mr. Hannemann. It is quite evident, therefore, that Mr. Hawley has not been watching the BEE JOURNAL very closely.

We have no desire to discourage any reasonable attempts to improve the race of bees, but we think the facts quoted from former volumes of the BEE JOUR-NAL are due to our readers, who are av-

pealed to for subscriptions to the importing fund, by Mr. Hawley. It cannot do any harm to give all the facts that are known about the stingless races of bees in South America. By all means, let them be imported and tried to the fullest extent. If they are of any value our experienced queen-breeders will very soon ascertain the fact.

We regret to state that Mr. G. M. Doolittle has been very sick for a month past. He is now able to sit up a little. His many friends will be glad to learn of his full recovery.

Three new bee papers are to be started for 1881—one in Wisconsin, one in California, and one in Louisiana.

The pinnacle of the dome of the court house at Gainesville, Texas, was last summer taken possession of by a swarm of bees. They still "hold the

Those who have subscribed for the Monthly or Semi-monthly, and may want to change for the Weekly, can do so at any time by paying the difference.

We send this number of the BEE JOURNAL to all our subscribers for the past year-kindly inviting them, by this notice, to subscribe for 1881.

Those who may have heretofore concluded that the Monthly BEE JOUR-NAL contained too much to be digested at a single meal, may find consolation in the fact that hereafter it is to be given in Four installments during each month, and will be more easily digested, and more acceptable in every way.

To our friends who will spend a few hours in working for the Bee Jour-NAL, we have concluded to make the following offers for all clubs sent in before Jan. 31: For a club of 2, weekly, we will present a copy of "Bee-Culture;" for a club of 5, weekly, we will give a copy of "Cook's Manual," bound in cloth; for a club of 6, we give a copy of the JOURNAL for a year free. Do not forget that it will pay to devote a few hours to the BEE JOURNAL.

♠ An old subscriber asks: "If I subscribe for the Monthly, shall I get all the matter contained in the Weekly, in a condensed form?" No; subscribers for the Monthly will receive the first weekly number (like this) published on the first Wednesday of each mouth, and will miss the next three numbers. Semi-monthly subscribers will receive the first and third weekly of each month (missing the second and fourth). Subscribers for the Weekly only will get all the reading matter. We advise all to take the Weekly who are keeping bees; it will nay them to do so. Any one who has subscribed for the Monthly or Semimonthly, can change to the Weekly upon paying the difference.

Southwestern Illinois and Southwestern Wisconsin Bee-Keepers' Association will meet in the Temperance Hall, Freeport, Ill., on Tuesday, Jan. 11, 1881. Mr. T. G. Newman, editor of the AMERICAN BEE JOURNAL, has consented to be present and will deliver a lecture on Progressive Bee Culture. Several other prominent beekeepers are expected to be present. A general invitation is extended to all interested in bee-culture to be present. terested in bee-culture to be present.

J. Stewart, Sec.

# GLEANINGS.

Novice is about to issue "Our Homes" in pamphlet form.

Doolittle sold his honey this year at from 18 to 22 cents per pound.

Novice has started a 5-cent lunch frames with other hives. counter at the depot in Medina, O.

A man by the name of King, in Northern Georgia, claims to have a patent on division boards, and threatens to prosecute those who use them. Novice emphatically, but truthfully, denounces this claim as absurd. There is no patent on division boards; never was, and never can be.

Chinese Bees, -Mr. C. D. King, a missionary in China, expects to return to America and bring some Chinese bees with him. He describes them thus:

"These bees in the bottle before me are more slender, and but little longer than the common house-fly, which is so plentiful with you. This latter pest is than the common house-ny, which is so plentiful with you. This latter pest is as scarce here as are the bees them-selves, if not more so. The head and thorax of these bees before me are black. Their waists are a reddish yellow, but the abdominal portion for more than half its length is black, marked with three white stripes across the back, with three white stripes across the back, with a slight pencil-mark, apparently meant for another stripe, near the extremity. On the under side, the yellow predominates, and takes the place of the white, so that they seem to have black stripes across the yellow. Their wings are white and transparent, with a very delicate throws they are released. By brown stripe along the outer edges. looking closely, one can also see a brown net-work traversing the delicate white wing. On the under side, their black heads and thoraxes seem to be covered with a white down or fuzz.

Bees and Honey in Florida.— W. S. art remarks: "The honey flow here, Hart remarks: flatt remarks: "The honey flow here, instead of being continuous, is divided into 4 seasons, with 2, 3 or 4 weeks of drought between. The honey here is as smooth as any in the North, and most of it as light-colored; in fact, our cabbage palmetto honey, which forms the history of the squaper hand. bage palmetto honey, which forms the big crop of the season, is so smooth and so light-colored, that many fear that it will not sell in the North, on account of consumers thinking it a manufactured article. We have but one crop of dark honey, and that is the last one of the season, and is used to feed back during the next spring. As to the profits here, I fail to see why they should not be far greater than in the North, as we have to got one expense to winter, and we never go to no expense to winter, and we never lose on account of the cold. The bees increase very fast, and we never have a year without a good crop of honey. We can ship our honey to any of the big markets by water, which is always cheap transportation; and as we have more good pine growing in Florida than in any other State in the Union, hive lumber is cheap.

# BEE-KEEPERS' MAGAZINE.

Comb Foundation .- Dr. Brown remarks: "A correspondent desires know whose foundation is the best. there are 'many persons of different minds,' it is quite likely that all may  $b\epsilon$ minds,' it is quite likely that all may be best. I have tried the flat-bottomed, the wired, that with tin base, that made on the Root machine, with only the outline of the side-walls, and that made on the Dunham, with the high side-walls and with sufficient wax around their base to enable the bees to complete the entire cell-wall, and I must say, without a moment's hesitation, that the Dunham has, thus far, proved the most satisfactory. I have not found it to sag: the bees soon set to work on it and build it out in much less time than the other takes. consequently it is soon filled with brood

While the Dunham, I believe, is sold for the same price as the other sorts, it greater confidence is really worth more, from the fact that they are engaged.

it is more difficult to make. The deep depressions in the rolls of the machine, to impress the high side-walls, make the sheets of wax more difficult to deliver from the rolls than when made on machines that give the mere septum of the comb and the mere outlines of the base

of the cells.
"By the use of foundation we can always secure straight combs, which is a desideratum in a large apiary where it is often necessary to exchange

Two Queens in a Hive.—A. H. Fra-enburg says: "I think I can throw a denburg says: "I think I can throw a new ray of light on this subject, which is now-a-days attracting some attention among bee-keepers. I have come to the conclusion that there are but just two causes or conditions in which two laying queens will be found in a hive at oncethe first is the superseding of an old and failing queen, in which case each queen seems to have a sort of reverence for the other; the second condition is that the bees in one part of the hive do not know at all times what is going on in another part of the hive. This assertion may raise a storm of opposition among the fraternity, but I believe I have the positive evidence to support it.

# BEE-KEEPERS EXCHANGE.

The Future for honey production, says П II. A. Burch, "wears a rosy tint, since it is more than probable that all the than probable that all the honey we can raise for years to come, will command good paying figures. Honey at 10 cents per lb. pays the spe-cialist who is favorably located, better than wheat at \$1 per bushed does the farmer; and when honey sells readily at 18 to 20c. per lb., the relative profit will be obvious to all. Every occupation is invested by many difficulties, which must be met and overcome; that the apiarist is, we feel sure, as free from them as any other calling."

Referring to D. A. Jones' plan for obtaining surplus, the editor says: "We have experimented a little in the direction indicated by friend Jones, and canfrom indicated by friend Jones, and cannot therefore think highly of his plan. For in the first place, we do not understand in what way the yield is to be greatly increased, and secondly, the perforated zinc or tin will not materially history the large from data given the large from the hinder the bees from depositing pollen in the frames or boxes thus placed be-tween the brood. Holes through which the queen cannot pass, greatly retard the passage of the workers, and, if used to keep the queen from leaving with the swarm, the hole covered with perforated material must be from 4 to 6 inches square, or the bees will smother, and in hot weather such an opening will hardly suffice.

# BEE-KEEPERS INSTRUCTOR.

Mr. S. D. Riegel has sold the *Instructor* to W. Thomas & Son, and retires because of other pressing duties. The Salutatory of the new editor is good.

Imported Queens.—The retiring editor, writing upon the desirability of obtaining imported queens, says: "If real improvement is desired, why not get a home-bred queen from a reliable breeder? one possessing in the highest de-gree those qualities which are so much sought after by our best bee-keepers. I would much rather risk the introduction of a good home-bred queen, possessing the best traits of character, into my apiary, with a view of continued improvement, than an imported one whose traits of character or good quali-ties are not known."

The National Convention,—The North American Bee-Keepers' Eleventh Annual Convention, which met at Cincinnati on the 28th of September, seems to have been of unusual interest. The meeting was well attended by the leading apiarists of the country, and a commendable degree of interest was manifested by the members of the Association. Everything passed off with zeal and harmony, and much was done that is calculated to encourage bee-keepers all over the land to move forward with greater confidence in the work in which The National Convention. greater confidence in the work in which

# Conventions.

# Madison County, Ind., Convention.

Onite a number of the most enthusiastic bee-keepers of Madison county met in the City Clerk's office at Anderson, Nov. 5th. The meeting was called to order by Mr. James Mahan, who stated that the meeting was called for the purpose of forming an association of the bee-keepers of Madison county. He hoped the meeting would be a success. He was satisfied that there were enough bee-keepers in the county to make a good association, if ty met in the City Clerk's office at Anderson, Nov. 5th. The meeting was county to make a good association, if they were called together. There were a large number of bees in the county, but the greater part of them were in box hives, or patent hives of all conceivable shapes and sizes. He was satisfied that this could all be remedied by the forming of an association. He therefore moved that the meeting proceed to a moved that the ineeting proceed to a permanent organization, proposing the name of A. J. Davis as President, who was duly elected. Mr. G. Hall was made Vice President,

James Mahan, Secretary, and F. M. Williams, Treasurer. By resolution, the society is to be known as the Madison County Bee-Keepers' Association. A County Bee-Keepers Association. A constitution and by-laws, similar to those of the State Association, were then read and adopted. Mr. J. G. Brown was called, and read the following:

# Hints to Beginners.

The old opinion, which ought to be entirely exploded, that bees will take care of themselves, and bring us large returns for little or no investment of capital or labor, is still a stumbling block to prosperous bee-keeping.

Ignorance of the business, then, is the

cause of a large proportion of ill success cause of a large proportion of ill success. What then is essential, is a thorough knowledge of the business, plenty of application and hard work. Much useful information may be obtained by reading the best bee journals and best bee books, but actual practice in the apiary is indispensable. Many persons are naturally unlit for the business, from archive and inconvention of the proposition of carelessness and inaccuracy about their work. I know of no out-door work where so much depends on the right thing being done at the right time and in the right way.

Avoid the common blunder of rushing into bee-keeping just after there have been one or two good seasons. The fact is, that an extra good yield is usually followed by a very moderate or

Beginners should purchase but a small number of colonics at first, and the bees will increase as fast as their knowledge will increase. Buy always the best that can be found, even if they cost more. for it will often pay you the first season. Spring is the best time to buy bees, for then they are through wintering and you have not much risk, and they will then be a profit to you. Use some good movable frame hive, for with the box hive the best results cannot be obtained.

A very great hindrance to the success A very great innumeror the success of many who would like to have bees, is fear of the sting in handling them. Every beginner should supply himself or herself with a good bellows smoker. for it is as necessary to the bee-keeper as a blow is to the farmer. Then, by a for it is as necessary to the bee-keeper as a plow is to the farmer. Then, by a little practice you can handle bees as easily as any of your stock. There is a difference in the quality and prolificaness of different queens, and different families of black bees. Some are more vindictive and more difficult to manage them afters: 20 maintains. The difference is not than others. than others. The uncerence is not in the treatment they have had, but in the blood. The same is true of Italian bees. While, as a rule, they are more peaceable and every way more easily handled than black bees. I found in my experience this season that t Albino bees are still more peaceable.

In successful bee-keeping more depends on the bee-keeper than on the hive, or the particular strain of bees; in order to succeed in the pursuit, a good degree of intelligence is needed. but a man may be intelligent in other things, and be a flat failure as a beebecome thoroughly acquainted with the bees' instincts, so as to know with approximate certainty

just what the bees will do under any circumstance. I do not believe that any one will succeed as an apiarist who has not a gennine love for bees. The successful bee-keeper must feel enough interest in his bees to know at all times winter and summer, their exact condition, and he must be careful to do for them what needs to be done, and to do it at the proper time.

As my conviction is in favor of chaff hives, and out of door wintering, I face all the hives to the east or south, with the bottoms of the hives three inches above the ground. I remove all the frames but those covered with bees and put in the division boards each side, or chaff cushions, and also on top of the frames place chaff cushions. Then your bees will stand the most severe winter. But to those who have no chaff hives. I would recommend covering the hives with flay straw or stack corn fodder, and will amply pay for time and trouble.

Frank L. Dongherty, delivered an address after which the following resolution was passed: "Resolved, that the thanks of this association be tendered Frank L. Dougherty for meeting with. and assissting in the organization of the association.

The meeting then adjourned till 10 o'clork the next day. On re-assembling the minutes of the previous meeting were read and approved. The attendance was much larger than on the pre-Several good papers were By discussed. There was a f enthusiasm shown. The vious day. read and fully discussed. There great deal of enthusiasm shown. meeting adjourned to meet on Saturday. December 18, 1880.

James Mahan, Sec.

# Southern California Convention.

The Southern California bee-keepers the southern Canforma bre-keepers convened at Los Angeles. Oct. 20, at 10 a.m. The President, C. J. Fox, not being present, Mr. J. S. Harbison was elected temporary chairman, and N. Levering Secretary.

Mr. Levering stated that the object of the meeting was to give an opportunity for exchanging ideas, and the more thorough organization of the honey producers. The boundaries of the district were decided to be the same as the The boundaries of the district boundaries of the Fourth Congressional District.

On motion, the chair appointed a committee on programme for business of convention, as follows: L. S. Butler, Frank Flint and C. N. Wilson.

The election of officers resulted as

follows:

Provident -d. E. Pleasants, of Anahem. Vice Presidents J. S. Harlinson, of San Dego; A. W. Hale, of San Bernardino; J. W. Wilson, of Pasadena; R. Wilkons, of Ventura; Frank Flint, of Santa Barbara; G. M. Harimston, of Vesalia. Secretary J. A. Haskolt, of San Fernando. Corresponding Secretary—C. J. Fox, of San Diego, Treasurer—E. F. Spence, of Los Angeles city.

Mr. Flint was called upon and read the address of C. J. Fox, after which a motion was made and carried that the address be placed on file and furnished

# President's Address.

Fellow Bee-Keepers:--It has been found by experience that, in most occupations, co-operation is exceedingly useful, and of late years almost a necessity. It is especially advantageous to farmers and producers. There are fruit growers', wool growers', wine growers', and other associations, the members of which meet from time to time for consultation and to arrange plans for mutual counsel and assisstance.

During the past five years, the beekeepers allover the country have formed county. State and national associations, at times and places, where much good has been done by exchange of ideas and opinions, and by comparison of different methods of managing bees, securing honey, and marketing it in the best

Keeping bees and obtaining or as we say, raising honey have been practiced by people in all ages and countries, and at times in the past, honey has been a more important article of food than now, when so many other articles are used as sweets, few of them, however,

so healthful as pure honey is.
But past history does not inform us

the last five years. All of us can remember the commencement of the presentera of scientific bee-keeping and its wonderful progress from small be-ginnings to its present position, as one of the important industries of our country, and especially of Southern California. San Diego county, where I reside, has the largest number of beekeepers, and produces the largest amount of honey of any county in the State, or perhaps of the same popula-tion in the world, and I may be pardoned for referring to its progress as an illustration. The business commenced in 1871 by Messrs, Harbison & Clark bringing there 100 colonies of bees. There had been a few there before, but scattered about, very little attended to, and only used for home consumption. This was the first attempt at establishing an apiary or making a business of bee-keeping. At present Messrs, Har-bison & Dowling are owners of over 3,000 colonies of bees, and the total crop for the present year is 310,000 pounds. They have shipped to the various markets in the Eastern States and California in the gastern States and Canfornia in the year 1880, 265,000 lbs. and have on hand yet to ship about 33,000 lbs., all comb honey, except about 2,000 lbs. In 1874-5 a good many others engaged in the business, and in 1878 there were over 20,000 colonies of bees in the county, and the export of honey exceeded 2,000,000.

The following tigures represent as nearly as I can obtain them, the condition of the business the present year: San Diego county had March 1, 1880, as returned to the assessor, 331 bee-keepers, 15,621 colonies of bees, and has exported, including the amount now in store in the city of San Diego, 418,700 lbs., of comb honey and 488,700 lbs. of extracted honey in barrels and cans. A considerable amount has not been brought in, and the total product will be about 1,000,000 pounds. I could not obtain exactly the number of colonies of bees at present, but Mr. Horbison and I estimate it at from 24,000 to 25,000.

Santa Barbara county, by a report from Mr. Frank Flint, Secretary Bee-Keepers' Association, had March 1, 1880, 31 bee-keepers, 1,757 colonies of bees, and has produced for export this season 257,800 lbs. of honey, nearly all Season 251,500 hs. of honey, hearly an extracted. The number as estimated October 1, is 3,655 colonies.

Ventura county, by a report from R. Touchton. Secretary of the Bee-Keepers'

Association, had last spring 70 beekeepers, about 4,600 colonies of bees, and has produced for export 700,000 lbs of extracted honey. The number of bees at present is estimated at 7,000 colonies.

San Bernardino county, by report from M. Segurs, Secretary Bee-keepers Association, has now about 6,000 colonies of bees, and has produced about 350,000 lbs. of extracted and 100,000 lbs.

comb honey. The totals from four counties show that there are at present over 41,600 colonies of bees, and that the product the present year is about 2,315,000 lbs, or the present year is about 2,315,000 lbs, or the present year is not the present year.

the present year is about 2,315,000 lbs, of honey, or 1,157 tons. The return from Los Angeles county would very much increrse these figures.

An industry that has grown in so short a time to such large proportions, naturally is not so well conducted as one that has been of slower growth. Thus we see a good many different kinds of hives in use, different methods of handling bees, of taking out honey, of packing, shipping, and marketing it, and a good deal of complaint among dealers, of the poor condition it is received in for market, and among producers, of unrenumerative prices. ducers, of unremnuerative prices

I leave the question of management of the apiary to others more able than of the apray to others more and than I am to discuss it; but, having had considerable experience in marketing, will mention a few points that may be studied with profit. For foreign shipment, a well made, iron-hooped barrel, holding not over 15 to 20 gallons, is the coffest extractive, where the suffer holding not over 15 to 20 gailons, is the safest, strongest, most easily handled, and most economical package. New tin cans, holding 60 to 100 lbs., and well boxed, are very good, but more costly, and not so acceptable to the European buyers. Small cans, of course, suit the Arizona and other retail trade. It is a whether bee-keeping was ever pursued mistake to put good honey in old tin as systematically as it has been during cans. The loss by leakage, breakage.

and unattractive appearance, more than makes up for the saving in first cost. As to comb honey, the Eastern dealers inform me that small packages sell better than large ones, though I know many think otherwise. At all events, they should be strong, neat and well packed. A great deal of honey loses, not only in weight, but in price, by being badly

In regard to shipment, our railroad freights are so high that we can scarcely ship overland in competition with Eastern producers and realize any profit; but ocean freights are cheap, though slow, and the saving is of itself a good

profit to producers.

It is a mistake to overload the market of San Francisco while there are so many others, for it causes low prices general disappointment. crease of our industry has been greater than the demand, and every one interested should do all he can to make more markets and increase the consumption of honey

of honey.

A good deal has been done in this way. Two years ago I made direct shipments to Europe to the amount of over 150,000 lbs. Although it did not bring as good a price as I expected, yet I learned that but for this and other historyte the surface of the shipments, the price in San Francisco would have fallen far lower than it did. and would have been nominal.

Mr. Gilchrist read an article on floriculture, at the same time exhibiting specimens of the different plants, which were placed on file for publication.

Mr. J. W. Wilson being called, read an article on "A Step Backward in Apiculture."

Adjourned until 9 a. m.

# THURSDAY, OCT. 21.

President Pleasants in the chair. Mr. Barber's article on apiculture was read and placed on file.

and paced on the.

Dr. Galny spoke for some time on various subjects in apiculture.

Mr. Harbison gave some of his experience in the bee business in California, and gave the association many points of interest, both in the management of the apiary, and also in the plan of marketing honey. He thought the mode of putting up honey for different markets should be in different packages. He placed great stress on the proper euring of extracted honey, and in having comb honey in straight full combs and neat, clean frames.

Mr. Levering read an essay on the industry of honey producing.

# AFTERNOON SESSION.

Mr. Harbison was requested to write the next annual address, with Mr. Flint as alternate.

Mr. Levering had framed an act to be presented to the legislature, (after such modifications as the convention saw fit to make), for the suppression and ex-termination of foul brood. The same was referred to a committee, with power to act in the matter, without further instruction. The committee being C. N. Wilson, L. S. Butler, N. Levering X. Wilson, L. S. Butler, X. Levering and J. E. Pleasants. Friday, October 22, 10 a.m. President

J. E. Pleasants in the chair. The subject of freights on packages was discussed, and left to local organizations.

The Secretary read an article from the New York Argus, entitled "The Stingless Honey Bee."
On motion, the executive committee

was authorized to co-operate with the vice-presidents of the different counties in gathering statistics relative to present crop and also of the crop of 1881; the vice-presidents reporting, from time to fime, to the committee, and they in turn reporting the aggregate to each of the vice-presidents. An invitation was extended to all apparists to communicate anything of importance to the committee.

The meeting then adjourned until fair eek, 1881. J. A. HASKELL, Sec.

The Michigan State Bee-Keeners Convention was held at Lausing, on the Sth and 9th ult. Prof. A. J. Cook was elected President, and T. F. Bingham was re-elected Secretary. The proceedings were received too late for this issue. but will appear in our next Weekly.

# Welcome to the Weekly Bee Journal.

We give the following as samples of the many words of welcome given to the Weekly BEE JOURNAL:

1, for one, am pleased with the "new departure," and although my subscrip-tion runs to August next, I gladly pay the difference between the monthly and the difference between the monthly and the weekly, believing I can more con-scientiously welcome its visits. I have long been of the opinion that monthlies were behind the spirit of the times: events transpire so rapidly that to keep posted we must have the press going all the time, and as you have promised us all the cream of the current events, we an the cream of the current events, we will mix it ourselves with a little honey, and we shall certainly have a rich feast. I wish the JOURNAL and its editor a "Happy New Year."

JAMES D. CHADWICK.
Lonisville, Kansas, Dec. 9, 1880.

The progress of apiculture is assured by the announcement of the birth of the Weekly American Bee Journal. I would sooner miss my dinner once a week than do without it. E. Drane. Eminence, Ky., Dec. 7, 1880.

Fifty-two times a year is none too often for such a welcome visitor as the American Bee Journal.

WM. A. OHAVER.

Monmouth, Ill.

I am highly pleased with the prospect of more frequent visits from my favorite bee paper, and hope you will be amply rewarded in your proposed new arrangement. R. M. Tankesley. Chattanooga, Teim., Dec. 6, 1880.

I wish you great success in the publication of the BEE JOURNAL weekly. It is a great undertaking—but one we shall all appreciate—to give us fresh apicultural news every week. It is just what is needed, and is real progression.

N. P. ALLEN.
Smith's Grove, Ky., Dec. 2, 1880.

The American Bee Journal is indispensable. Send me the Weekly for next year.
Gananoque, Ont., Dec. 8, 1880.

Bee-keepers everywhere should give the American Bee Journal their constant support, as a weekly, so that it may become a success, and be an ad-vantage to its owner as well as to its thousands of readers. H. H. Brown. Light Street, Pa., Dec. 8, 1880.

I am greatly pleased to learn that the BEE JOURNAL is to become a weekly next year.

D. A. PALMERTON.

Collins, N. Y., Dec. 9, 1880.

The BEE JOURNAL is so interesting and valuable as a guide to scientific beekeeping, that I cannot do without it.

H. N. CORNELIUS.

Hope, Ark., Dec. 11, 1880.

The thought of a Weekly BEE JOUR-NAL is a welcome one here, I assure you. JAMES HEDDON. Dowagiae, Mich., Nov. 20, 1880.

I am delighted with the idea of having a weekly paper devoted to bee-culture.

J. F. McCoy.
Van Wert, O., Dec. 11, 1880.

I cannot do without the BEE JOURNAL even one week. I think more of it than any paper I take.

II. M. WILLIAMS, M. D. Bowden, Ga., Dec. 10, 1880.

I am highly pleased to have the BEE JOURNAL come out weekly. More than once have I "delayed operations" for the monthly to put in its appearance. Friend Newman, you have taken a step that the bee-keeping fraternity may well feel proud of: I for one feel thankful that we are to enjoy its visits weekly instead of monthly. Allow me to congratulate you for the enterprise you have displayed. WM. H. GRAVES. Duncan, Ill., Dec. 6, 1880.

I rejoice that you are going to give us a weekly. If you evereonclude to issue it daily, count on me for a subscriber. I wish you success in the present undertaking. J. S. HUODES.: Macon County, Ill.

I wish to add my praises on the tone and quality of the AMERICAN BEE JOURNAL. I have long given a silent approval to the many encomiums pronounced upon it. E. L. Dresser.

Shopiere, Wis., Dec. 13, 1880.

Sample copies of the Weekly BEE JOURNAL will be sent free to any names that may be sent in. Any one intending to get up a club can have sample copies sent to the persons they desire to interview, by sending the names to this office.

# Bees in Borneo and Timor.

A DEVON BEE-KEEPER.

Having recently perused Mr. Spencer St. John's very interesting work on Borneo, published in 1862, under the title of "Life in the Forests of the Far East," I have made notes of several passages relating to the apian aborigines of that magnificent tropical island:—

Speaking of the agricultural pursuits of the "Sea Dayaks," Mr. St. John says—"They obtain beeswax from the nests built on the tangung tree, and climb the

—"They obtain becswax from the nests built on the tapang tree, and climb the loftiest heights in search of it, upon small sticks which they drive in as they advance up the noble stem that rises advance up the none stem that lises above one hundred feet free of branches, and whose girth varies from fifteen to twenty-five feet. Once these pegs are driven in their outer ends are connected driven in, their outer ends are connected by a stout rattan, which, with the tree, forms a kind of ladder. It requires cool and deliberate courage to take a bee-hive at so great an elevation, where, in case of being attacked by the bees, the almost naked man would fall and be dashed to atoms. They depend upon the flambeaux they carry up with them, as, when the man disturbs the hive, the sparks falling from it cause, it is said, the bees to fly down in chase of them instead of attacking their real enemy, who then takes the hive and lowers it down by a rattan string. The bees escape unhurt. This plan does not appear to be as safe as that pursued by the Pakatan Dayaks, who kindle a large fire under the trees, and, throwing green branches upon it, raise so stifling a smoke that the bees rush forth, and the man ascending takes their nest in safetir. Both these premiums are green

ing tribe venturing to help himself to some of this apparently wild honey and wax would be punished for theft." This is the first hint that is given of bees being considered in any respect as bees being considered in any respect as private property, but the following passage would seem to indicate that the domestication of the honey-bee is not altogether unknown in the island:—
"During the night, our rest was much disturbed by bees, which stung us several times, and Mr. Lowe, with that acuteness which never deserts him in all most long of intrival history arguments." acuteness which never deserts him in all questions of natural history, pronounced them to be the 'tame' bees, the same as he had last seen thirteen years ago among the Senah Dayaks, in Sarawak. About midnight we were visited by a big fellow, who, our guides assured us, wanted to pilfer; but we found next morning that he had come to complain of his bigge having lyear almost all. of his hives having been plundered. On inquiry, we discovered the man who had done the deed. He was fined three times the value of the damage, and the amount handed over to the owner.

amount handed over to the owner.

In a subsequent part of his journal of the same expedition, our author says—
"I never was in such a country for bees, they everywhere swarm in the most disagreeable manner, and ants and other insects are equally numerous."

When on their return and nearly stayted, the party had "a very happy stayt for while pressing under a fine fafind, for while passing under a fine ta-

doubt that these are the bees referred to by Mr. St. John. On examination 1 found them half as long again as Apis mellifica, and their brood comb proportionably thicker. They were in fact, a variety of the magnificent Apisdorsata, which is described as flourishing abundantly throughout the great Indian peninsula, from Cape Comorin to the Himalanes, as well as in Capta n layas, as well as in Ceylon."

Mr. Darwin subsequently introduced me to Mr. Wallace, to whom I am indebted for the following particulars:—
"In Borneo and Timor the wax forms an important article of commerce. The combs hang on the under side of horizontal limbs of lofty trees, often one hundred feet from the ground. I have seen these torsether as above, and they hundred feet from the ground. I have seen three together as above, and they are often four feet in diameter. The natives of Timor I have seen take them. They climb up a tree carrying a smoke torch made of a split creeper bound up in palm leaves, and hanging by a rope from their waist. They cover up their body and hair carefully, but their arms and legs are bare. The smoke directed on the comb makes the bees fly off in a cloud as the man approaches. He cloud as the man approaches. He sweeps off the remainder with his hand and then cuts off the comb with a large knife, and lets it down to his companions below by a thin cord. He is all the time surrounded by a cloud of bees, and though the smoke no doubt partly

Manner in which Bees in Borneo and Timor build their combs

pang tree we noticed the remains of a bees nest scattered about, and every particle was eagerly appropriated. From the marks around it appeared as if a bear had climbed this lofty tree and torn down the nest to be devoured by its young below, as there were numerous tracks of the smaller animals around, but whether the comb had been sucked by the bears or not was very impaterial to our men, who rejoiced in material to our men, who rejoiced in securing the little honey still clinging to

That wild bees are exceedingly abundant in the forests and jungles of Borneo may be inferred from the foregoing pasmay be inferred from the foregoing passages as well as from the nullerons references to parties of native "wax-hunters," which occur in almost every chapter of the work. Although no clue is given by Mr. St. John to the identity of the Borneon honey-bee, or any information as to the manner in which it builds its nest, I am enabled in some measure to supply the deficiency from other sources.

Some half dozen years ago I received from Mr. Charles Darwin, the distinctions of the sources.

pang tree we noticed the remains of a bees' nest scattered about, and every particle was eagerly appropriated. From the marks around it appeared as if a bear had climbed this lofty tree and torn down the nest to be devoured by its young below, as there were numerous tracks of the smaller animals around, but whether the comb had been spread by the bears or not was very inthe dry season answers to our winter, as the drought is very severe and much of the foliage is decidnous. Encalypti are the most common trees, and their flow-ers I suspect supply the bees with their honey. In Borneo combs are placed in a somewhat similar manner, perhaps formed by the same species. The only bee I have seen domesticated in the a somewhat similar manner, perhaps formed by the same species. The only bee I have seen domesticated in the East is one at Malacca; the natives hang up bamboos and hollow logs for it, but it is, I believe, not a true Apis, as it makes clusters of large oval shells of black wax."

For the American Reg Journal

# The Last Honey Season in California.

HOLMES & SCOTT.

As we see a great many individual reports from bee-keepers in the eastern States, we thought a report from this locality might interest some of your readers.

The season of 1879 was a complete failure and left us with 75 colonies in The season of 1879 was a complete failure and left us with 75 colonies in the fall, which the cold winter following reduced to about 54. We then bought 6 weak colonies, together with a lot of hives of the same pattern as our own. We increased these 60 colonies to about 100, and extracted about 7,000 lbs. of honey. This result was not as good as we expected, and not as good as we bad a right to expect from the amount of rainfall we had last winter, which gave such bounteous crops of everything else. Our first general extracting, early in May, gave us about 2,000 lbs., from about 75 colonies; the remainder being nuclei too weak to extract from. Our next week's extracting was only 1,200 lbs., and the next 600 lbs.; then we skipped a week and only extracted about 700 lbs.; next we skipped two weeks and got about the same.

Now for the reason, or our theory of it. About the time of our first extract.

Now for the reason, or our theory of . About the time of our first extractit. About the time of our first extracting we had an intense hot wind, lasting several days, and after that we had fogs and such cool weather that honey did not flow much. The whole mountain side was one sea of flowers and our bees, though very strong and working as well as bees ever worked, could not fill up the hives as they did two years before, when we took from our strongest colonies 40 to 50 lbs. of honey per week for several weeks in succession.

nies 40 to 50 lbs. of honey per week for several weeks in succession.

Our colonies are now in splendid condition for winter, and our only preparation for keeping them over is to close the entrances to about two inches, shut up the ventilators, put stones on the covers to keep the wind from blowing them off, and if they have honey enough they are all right. In this we have you eastern bee-keepers at a disadvantage.

Now Mr. Editor if this is too long.

Now, Mr. Editor, if this is too long, boil it down; if good for nothing do not publish it—but send us your valuable JOURNAL another year, because we like very much.

Los Angeles, Cal., Dec. 21, 1880.

For the American Bee Journal.

# Bees Deserting Winter-Quarters.

E. A. MORGAN.

sages as well as from the numerous sparks falling from it cause, it is said, the bees to fly down in chase of them instead of attacking their real enemy, who then takes the hive and lowers it who then takes the hive and lowers it so make cape unhurt. This plan does not appear to be as safe as that pursued by the Pakatan Dayaks, who kindle a large fire under the trees, and, throwing green branches upon it, raise so stiding a smoke that the bees rush forth, and the man ascending takes their nests; they are considered private property, and a Dayak from a neighbor
as when the man disturbs the hive, and lowers it is said, the man is sparsed to be a parties of native. "was a set is one at Malacca; the natives hang phanboos and hollow logs for it, but it is, I believe, not a true Apis, as it can be allowed by Mr. St. John to the identity of the Borneon honey-bee, or any information as to the manner in which it signifers the inlives at this season of the was."

I motice on page 3 of BEE JOURNAL for Issi, Mr. D. S. Kelley asks why his last is one at Malacca; the natives hang phanboos and hollow logs for it, but it is, I believe, not a true Apis, as it believe, not a true

I am conducting careful experiments in wintering, and believe that if well understood, we need have no trouble. My bees had no fly from Oct. 26 until Christmas; being 52 days. They then flew all day and cleansed themselves nicely. There were not over a dozen dead bees in any hive; no bees flew away or fell in the snow, and at night all were quiet and dry. They were all rended on the summer stands early, and away or left in the show, and at light all were quiet and dry. They were all packed on the summer stands early, and had several flights afterwards, before it froze up. The weather during 52 days was severe, several times going as low as 20 and once 34 below zero; one or as 20—and once 34—below zero; one or two showed ice in entrance but nearly all are dry. Will Mr. K. inform us through the Journal, whether his bees have been disturbed in any way since it froze up, also state whether they have been moved from the summer stand to another location, or the hives turned around to face a different direction or not; also at what time the first frosts occurred, causing the queen to cease laying. I am anxious to hear of all disasters of this kind that we may trace up the trouble and benefit ourselves and if possible find the cause.
Arcadia, Wis.

# Light vs. Dark-Colored Italian Bees.

o, o, Poppleton.

I see that Mr. Dadant, in a couple of articles published in different bee papers, takes issue with the opinions of several bee-keepers who expressed themselves at the Cincinnati Conventhemselves at the Cincinnati Conven-tion as preferring the light to the dark strains of Italian bees. I have also noticed that for several years back nearly every writer in the bee peri-odicals, who expressed an opinion at all, seemed to think the dark or leather-colored bees would store the largest amount of honey, other things being equal. My own observation seeming to point so decidedly the other way, led me to make personal inquiries of a large number of practical bec-keepers while number of practical beckeepers while at Cincinnati, as to their individual experience, and I think, without a single exception, all I spoke to (some 15 or 20 in number) expressed a very decided preference in favor of the light-colored bees. Several went so far as to say that "The claim that the dark-colored strains of Italian bees are the best honey-gatherers is all bosh, and the reason of the claim being so persistently reason of the claim being so persistently made is on account of its being so much easier for queen-breeders to rear dark than light queens." Of course I know nothing about the truth of the last opinion

In my own apiary 1 have for years kept a tablet in connection with each of my colonies, on which is recorded, besides other things, the grade of both queen and bees. I divide the bees into four grades—the No. 3 are those that I do not feel certain about their purity, on account of being so dark and irreguon account of being so dark and irregular in coloring, although showing all three bands; the No. 2 are those I am satisfied are pure, but somewhat dark in color; the No. 1 are the light-colored, pure bees, and the X No. 1, are the few colonies that in addition to being you light-colored, are also very regular in color, size, shape and marks. Of course 1 aim to rear my young queens from these latter.

As I do not rear queens for sale, but devote my attention cutirely to the production of honey, I desired to breed the coming year from those queens whose colonies have given me the most honey, and have given especial attention to that point. The difference in favor of my lightest-colored colonies was so marked, that I got in the habit, during marked, that I got in the haut, during the season, whenever I lifted the cover from one of those colonies of saying to my assistant, "Here's an X No. 1 colony; we'll get lots of honey now," and we almost invariably did get more than the average amount of honey from those colonies.

President Newman, in one of his ad-

dresses at the Convention, gave beauty as one of the essential points of a queen, "So they will attract the attention of the fancier of live stock." This is all right so far as it goes but could be not have given another reason? For the

three or four years previous to this last year, I have kept as many bees as I could handle alone without assistance, and it has been one of my studies to so arrange everything about my apiary as to save as much labor as possible. The less time it took me to manipulate each hive the larger number of bees I could keep, and of course the more money I could make. A great many in the course is the more money I could make. could make. A great many of the operations of the hive requires the finding of the queen, and all bee-keepers will agree with me that the lighter in color the queen, the easier and quicker can she be found on the combs. If this was the only point of superiorty the Italians have over the blacks, it would namely repay us for their extra cost, and of course applies to the difference between light Italian queens and dark ones, only in a less degree. I do not doubt that I would save money by paying one dollar apiece more for young tested light-colored Italian queens than tor dark ones, all things being equal.

Williamstown, Iowa, Dec., 29, 1880.

# For the American Bee Journal. Importing Bees from Italy.

REV. A. SALISBURY.

With the bee-keepers of this country with the hee-keepers of this country it is yet no doubt an important question, whether we shall continue to import hees from Italy. The National Bee-Keepers Convention, assembled in Cininnati in November last, had before it the following as a test question:

Resolved, That the importation of Italian queens is no longer advisable, as an improvement of our present race of bees.

The resolution was laid on the table almost without debate. ...s "coming events cast their shadows before," it is not hard to divine the impression now resting upon the minds of our leading bee-keepers. The points of excellence so eagerly sought for by the enterprising So eagery songhetor by the enterprising American bee-master, viz.; Good honey gatherers, longevity, beautiful to look upon, gentle to handle, and good powers of endurance, are to-day so strongly developed in the American improved Italian bee, that Italy is surpassed.

It is no longer a question, the Italian bee of Italy is not a distinct race, yet many of us once thought they were. Later investigation proves the fact that there are as black bees in Italy as anywhere else, even in the vicinity of Rome itself. If the first Italians imported where ease, even in the vicinity of confi-itself. If the first Italians imported into this country were a superior race of mixed bees, and have been bred up to a standard of higher excellence and beauty in this country, why continue to import inferior queens to our shores? We want to hear from leading bee men of the country on this subject.

It new beginners are taught that nothing will do but queens reared from imported mothers, of course they must have them—must have what they order and pay their money for.

and pay their money for.

After this subject is thoroughly investigated, if found to be a step backward to drop the importation of Italian queens, let it be continued with great care, always to get the best Italy affords. Demand says what the character of the queens shall be that are supplied. If public demand says give us queens bred from imported Italian mothers, they must have them; or, on the other hand, if from the most excellent and beautiful improved. American Italians, they if from the most excellent and beautiful improved American Italiaus, they will get them. In a free Republic like this, the people are the sovereigns. While this is and will remain a fixed fact, duty demands that the truth fact, duty demands that the truth should be given through our bee papers, so as to educate the public mind to demand the best.

Progress is God's law, by infinite wisdom and an unseen hand reached down to earth—a sparkling gem. It is more than probable, with the improved Ital-ians we now have, and the Cyprian and Holy Land bees brought to our country the past season, we will in a few years have the finest bees in the world. Yankee enterprise and genius will combine the most excellent traits of all, and, we hope, drop the imperfections of their ancestry, leaving them on a foreign

Camargo, Ill., Dec., 1880.

# Qualities in Bees, Improvement, etc.

PROF. A. J. COOK.

To observing apiarists, and they are becoming very abundant in the United States, it is well known that some bees are far more valuable than others. Some colonies of bees, with no better chances than have others in the apiary. so far as the bee-keeper can see often two or three times as much honey The Italians give us more surplus than the German or black bees, and it seems the German or black bees, and it seems probable, though it may be too early to speak with certainty, that the Cyprian and Syrian races will surpass even the Italian in quantity of their stores.

At the National Convention, which lately convened at Cineinmati, the statement is the statement of t

ment was made that the light-colored Italian bees were superior to the darker than bees were superior to the darker ones, or, what means about the same thing, that the Americanized Italians are more valuable than the imported ones. This assertion seems to have been the voice of the Convention, at least the report gives no protest against

For one, I do not believe this state ment. In fact I feel very certain that it is incorrect. My attention was called to the matter seven or eight years ago. At that time two of America's most able bee-keepers—the late Adam Grimm and Mr. E. Gallinp—whose statements on matters pertaining to the apiary rarely needed other support than that given by their own opinion, both spoke out boldly in favor of the darker colored out bondy in favor of the darker colored Italians. Since that time I have closely observed, and have always found that they were correct. I believe this opinion is also held by such authorities as Chas. Dadant, G. M. Doolittle, James Heddon and T. F. Bingham. At the Michigan State Convention last week, this coinion was remainingly ensystined. this opinion was unanimously sustained by all who had observed carefully in

On the other hand, Mr. T. G. Newon the other hand, Mr. I. G. Newman, for whose ability and judgment I have great respect, believes that the so-called "Apis Americana," (of course this should be Apis Mellifica, variety Americana), is to be the coming bee, if it is not so now.

Now I wish to urge an opinion, which About wish to high and a very important one, too, to the effect that so soon as we cease to import bees we shall find that our apiaries are deteriorating. I have found with Mrs. Baker and others. that when I bought the beautiful light yellow bees which had been closely bred yellow bees which had been closely bred for a long time without any foreign blood being incorporated, that I had got bees that were as valueless as they were handsome. On the other hand, I have found my imported Italian queeus, which, though often as black as those of royal work. I repeat that these queens were very prolific, and their worker progeny always three-banded, though the bands were not of that bright yel-low which characterizes our Americanbred Italians.

Now I believe this matter is very easily explained and a good reason given for the facts as I have stated them.

All the European bees, and this is peculiarly true of the Italians, Cyprians and Syrians, are bred under the most From the rapid trying circumstances, increase of bees, the limited pasturage, and the fact that nature is for the most and the fact that nature is for the most part the breeder, with the three last mentioned races the struggle for life is intense. Color and beauty are of no account except as they aid their possessor. And so there is the most severe pruning. Those alone survive which can gather sufficient stores despite the drouth, and their numerous competitors.

Mr. Benton, who has spent the past summer at Larnaca, Cyprus, writes me that the drouth upon the island has been very severe, and that unless he had fed he would have lost all his bees. Such hard conditions must of necessity breed a race of bees which we cannot expect to rival.

Our American breeders will be very slow to adopt the severe pruning which nature practices with relentless hand in Italy, Cyprus and Syria. Our breeders humanskill provided for their survival

look to some fancied superiority, like white fuzz on orange shield, banded drones, golden color, etc. And we can hardly hope, because of such prejudice, ven were there wisdom sufficient, for that hard cold selection, which knows only genuine superiority, that nature always adopts.

I will, therefore, close by saying that the most progressive apiculture de-mands the frequent importation of these rigidly bred queens from Italy, Cyprus

Lansing, Mich.

[We are among those who have observed "that some bees are far more valuable than others;" at the recent meeting of the National Convention, in Cincinnati, were many old and intelligent bee-keepers who have observed it -some of whom have kept bees for more than a score of years for a livelihood; others who keep bees as a combination of recreation and profit; some who keep bees as breeders and to supply a public demand: while not a few keep them as a source of study and recreation alone. With all these persons, close observation, continual experiment, and discriminating judgment are proverbial. With the use of the movable frame contributed by the great Langstroth, and a close study of the scientific Manual by Prof. Cook, bee-keepers are advancing in their views as rapidly as science and research develops new truths. The unanimous verdict of the Cincinnati Convention, in favor of the light strains of American-Italians, was undoubtedly based upon discriminating observations.

We wish it distinctly understood, that while we believe the intelligent and discriminating bee-keepers of America have succeeded in breeding a strain or strains of bees equal, if not superior, to any to be found in Italy, we would not discourage any from importing, if an improvement is possible. But an indiscriminate importation, as is too much the case of late, may be the means of flooding the country with a lot of second rate queens, far inferior, but at a higher price than much of our really excellent improved stock. We do not doubt there are many fine queens bred in Italy, but we do believe none are better than some of our best. If some queens and some bees in Italy are light and others "black as those of the German race," is it not as those of the German race," is it not not only three banded workers, but those that could be counted on for right tion prevail? and has a purchaser any assurance that he is obtaining the better variety? We do not believe, with our careful and discriminating breeders, it is possible for our superior bees to deteriorate, but, rather, that we are on the higher road to perfection, and that strains may be developed to meet the most exacting exigencies.

Suppose, however, it should prove true, as now believed by many observing apiarists, that the bee of Italy is itself a cross, is it not quite possible, nay probable, that the years of careful and observant breeding in this country and portions of Europe, have more fully developed some of the better qualities possessed by one branch of the cross, while it has obliterated the undesirable characteristics of the other?

Undoubtedly "our American breeders will be very slow to adopt the severe pruning which nature practices" with bees, as with everything else. This is only another expression for "nature's survival of the littest." According to Mr. Benton, nature last season would

It is a question whether nature, in the course of her pruning processes, does not frequently perpetuate an undesirable feature at the expense of more desirable instincts and powers: for instance, in developing the physical formation of bees, during a long period of time, to withstand the hot, scorehing winds and frequent drouths of Cyprus and Syria, may it not have been at the expense of physical developments to enable them to withstand our northern climate, unless crossed with a hardy race, or acclimated by careful breeding through several generations? Or, may not nature, in the course of fitting bees to survive months of starving drouth, deprive them of that ambitious instinct to store large amounts of honey during a long and bountiful season of bloom? With the Italian bees, our honest breeders have perpetuated the best; many breed for certain charteristics-some to develop longer tongues, others to encourage amiability, a few want an increase in size, and the specialist would have bees that can gather honey all summer long; but the progressive bee-keeper of to-day wants all these qualities combined in the same bee, and what with our improved Italians, and perhaps a few features borrowed from the best of the Cyprian and Syrian bees, he will realize the fruition of his wishes.

The wise bee-keeper will buy the best home-bred, or breed from what  $h\epsilon$ finds best; do not depend upon "nature's severe pruning," for her hand is indeed relentless. The dogma of "the survival of the fittest," is antagonistic to civilization and progress, is fatal to education and science, and calculated to encourage slothfulness and barbarism. No successful stock-breeder, farmer, poultry-raiser or bee-keeper will be satisfied with what is left after nature has completed her priming.

Convention, M. Hayes, Esq., offered the following resolutions, which were unanimously adopted:

Resolved, That the importation of pure Italian, Cyprian and Holy Land bees into North America, ought to be encouraged for the sole purpose of adding new and different strains of blood to that the sole purpose of the sole purpose of adding new and different strains of blood to

that we already have.

2. That the strain of Italian blood we now have has reached a higher standard of excellence than is to be

found in the native home of the Italian.
3. That queens reared from pure selected home-bred Italian mothers, should command at least as high a market value as those bred from imported mothers, where pure Italian stock is the sole object desired.

The resolutions met our hearty approbation at that time, and we have bad no occasion to change our opinion since.

For the American Bee Journal.

# Stingless Bees of South America.

JOHN F. DIPMAN.

I am highly pleased with the new Weekly Bee Journal and think every bee-keeper should try to give the Weekly a good support. Allow me to congratulate you for the enterprise you have displayed.

On page 5 of the last Journal is an article on stingless bees of South America.

On page 5 of the last JOURNAL is an article on stingless bees of South America. Are the bees of South and Central America alike? Are our bees inferior or superior to the stingless bee of Central America? If not, it will not pay Mr. Hawley to import them, he will only lose his money. Mr. A. O. Moore, of New York, imported stingless bees from Central America, about 1860, and had them on exhibition in the office of the American Agriculturist in office of the American Agriculturist in

dead after the first cold weather.

In the American Agriculturist, Mr. Moore gives a full description with several illustrations of the bees and their combs. He says, that they cannot be kept with other bees on account of having no sting for self-defence. Mr. Moore was about 3 months in Central America and paid particular attention these bees

Fremont, Ohio.

[In reference to this scheme the .Imerican Agriculturist[says:

"It is proposed by W. S. Hawley to introduce the stingless bees of South introduce the stingless bees of South America as soon as a sufficient number of subscribers warrant the enterprise. The circular states that an article in an Albamy paper in September last 'was the first intimation the Bee Fraternity of the United States had that there ex-isted anywhere on the habitable globe

1--Queen Bec.

2-Side View

a species of the honey bee that has no stingers. It was because the 'Bee Fraternity' did not read the American Agriculturist, as we, in 1861, not only figured and described the stingless bees, but had a colony of the bees themselves on exhibition at our office when it was in water street. Figures 1 and 2 represent different positions of the queen bee of the *Jicole* variety of the stingless bees. Figure 3 is one of the workers."

Mr. Hawley was unfortunate in many expressions in his circular. Gleanings for January imagines that he stated that the Rev. W. F. Clarke was killed by a bee-sting on the back of his tongue, and having written to Mr. Clarke to know whether he was dead or not, received a long reply stating that he was alive and well, and that he "hoped to do a little more good in the world before leaving it." This was the result of Mr. At the last session of the National Hawley's awkward manner of expressing himself. He did not intend to say Mr. Clarke was dead, but a man who, later, accidentally got a bee in his mouth, which stung him, etc.

Then, again, Mr. King, in the Bee-Keepers' Magazine, complains of Mr. Hawley's bungling way of expressing himself, carrying the idea that Mr. King endorsed his project, which Mr. K. emphatically denies.

Now comes another circular from Mr. Hawley, stating that he will stay in Brazil two or three years, in the employ of the Brazilian government, "to introduce the mysteries of American beekeeping" into that country.—Ed.]

From the Prairie Farmer.

# Bee-Keeping as Woman's Work.

MRS. L. HARRISON.

Some women love to be dependent and to be compared to clinging vines, which are lifted into air and sunshine by sturdy oaks; there are others again who scorn dependency, and can stand erect guided by light from heaven and true womanhood. This kind of woman loves to be a producer and in olden true womanhood. This kind of woman loves to be a producer, and in olden time found abundant range in manufacturing cloth. Solomon says: "she seeketh wool and tlax, and worketh willingly with her hands; she layeth her hands to the spindle, and her hands hold the distaff." The use of steam has almost entirely dispensed with spinning wheels and looms from the household, so self-reliant women are prying into every nook to discover some other avenue where she can develope her mind and energy.

ventions, being regarded as superior beings or as ornaments of enough value to pay all admission fees, badges, etc. If we compete with the other sex in making pants or in teaching, we will be obliged to accept less pay than they do: but who ever heard of a pound of honey bringing less because it was produced by a woman? No "vines" had better embark in the business, or women of means, who know nothing practically of bee-culture, but purpose to hire the bees cared for by others, and expect to reap a rich reward from their investment; but any woman who can make good bread, pick a goose, milk a cow, or harness a horse, can make bee-keeping

a success.

We know a woman who is going out to wash by the day in order to earn money to purchase a colony of bees.

We opine that she will make bee-keeping a success as she is bright, smart and self-reliant. She has the misfortune to have a paralytic husband, and thus exerts herself to make a comfortable living, and educate a feeble son. All honor to her and other brave women

who never shirk the burdens of life.

There is nothing connected with beekeeping but what a woman can do as well, as the other sex. She should not be expected to manufacture her hives any more than a house-keeper to build her own house; but as hives, frames, and surplus boxes can be purchased cheaply in the flat, we know no reason why she cannot learn to nail them to-gether. We should have tried our hand at it long ago, if we had not a partner who is an expert at it.

No one should engage in the business expecting to find a "Bonanza." but any woman may reasonably expect fair returns for the money and time expended. One or two colonies is sufficient to commence with if your knowledge increases in like ratio with your bees, all will be smooth sailing and a prosperous voyage.

Peoria, Ill.

For the American Bee Journal.

# Spring Feeding-Spring Dwindling.

WM. S. BARCLAY.

These two subjects, although apparently so different, are so nearly related that we consider it not at all improper to treat of them together, some of our fraternity having gone so far as to insist that the former is even the cause of, or productive of the latter, assigning as a reason that feeding causes an undue flight of the bees in such seasons, as in many cases they are unable to return to their hives, and many being prevented from so doing, produce a decline in the population of the colony, and thus they account for spring dwindling. However we may dissent from this view of the case, it occurs to us that this unseasonable flight, as it is termed, may be the means of saving us from that other dismeans of saving us from that other dis-aster so much dreaded—dysentery— which I cannot look upon as a disease, but, as Mr. Doolittle well disposes of the subject, the unnatural condition of the organs of the bee consequent upon long confinement to the hive.

long confinement to the hive.

As to spring feeding, opinions do not differ so much on the subject itself, as to its time of commencing; how it shall be conducted; for what purpose it shall be resorted to; how long it shall continue, etc. When we have concluded to feed, it will be our first purpose to see that the hive and the bees are in proper condition for giving the feed. Our practice in the past has been like the following: We make our hive perfectly comfortable for the bees to go to any part of it when necessary, by the use of proper packing, suitable division boards, etc. We place the bees in the west side of the hive (hive standing to face the south), first having placed a chaff division board next the side-wall of the hive. As to this division board, it may not be amiss to say, that it is made by ning wheels and looms from the household, so self-reliant women are prying into every nook to discover some other avenue where she can develope her mind and energy.

Scientific bee-culture is an open field to all women of energy and brains; here is a free range for discovery, improve-

September, 1860; but they were found ment, and production. Why! we do ready for use the same as any other not even have to pay one cent to be addivision board. We leave only enough mitted to the membership of bee concombs for the bees to cover entirely, combs for the bees to cover entirely, then insert along side these combs another chaff frame; on the opposite side of this chaff frame we place our frame containing the honey we wish to feed, or a feeder of suitable kind containing either honey or sugar syrup, and an empty comb, the cells of which have been filled with water. We may then income the other framework in the cells of the containing the containin nsert another chaff frame, and if space still remains in the hive, it may be filled with wheat chaff. Let me here say, that I consider clean wheat chaff as a proper absorbent of moisture, superior to any packing I have ever used.

It may be asked why, at the time of It may be asked why, at the time of feeding, we have given a comb containing water. In reply we say, to prevent the flight of our bees in search of water which they consume very eagerly when being fed. Water may also be given in various other ways, as, for instance, small sponges may be filled and placed over the combs containing the bees and brood; cofton rares, may be saturated. brood; cotton rags may be saturated with water and hung in the same manner. A colony thus treated will be found to adhere more closely to their hives when being fed than they will do in the absence of water.

When the feeding is to be conducted as proposed, after the food and water have been properly introduced, the next important matter to receive attention is the careful covering of the combs. For this purpose we use a soft woolen quilt or blanket to securely cover the combs, and then place on top of this a box or frame 4 inches deep, filled with wheat frame 4 inches deep, filled with wheat chaff, observing carefully that no space is left open for the passage of a current of air through the brood combs. But little fear need be felt of making the bees too warm. Should such be the case, a portion of the top covering can easily be removed. After the hive has been placed in the condition described, been placed in the condition described, all that remains for us to do is to be watchful that at no time the feed or water supply shall be permitted to fall short, and when the condition of the colony and the state of the weather will permit it, place an empty comb for eggs between two of the brood combs, observing carefully that we have enough beas to entirate cover all the contri bees to entirely cover all the combs. The importance of keeping up the feedon a cold morning, and there ind the young larve which have been carried ont of the hive on a cold morning, and there find the young larve which have been carried ont of the hive during the night. This is also an additional reason why we insist that no more combs be given than the bees can protect, in which case loss of broad from being chilled will not

When, unfortunately, in some cases our bees have suffered from dysentery, we have found the best remedy we we have found the best remedy we could apply was a supply of water inside the hive; especially did we find this was the case when the bees had free access to artificial pollen, such as rye meal or other suitable substance. It is better in all cases where the colony has been severely affected with this trouble, to remove the soiled combs to a populous selection and in their place formish lous colony, and in their place furnish clean combs, and to do this even at a loss of brood combs of the afflicted colony. No danger need be apprehended in giving those combs to a strong colony, as they will soon clean them off without being at all affected. This is another reason why we cannot assent that dys This is another entery is a disease

Beaver, Pa., Dec. 21, 1880.

The Rock River Valley Bee-Keepers' Association will hold their annual meeting the second Tuesday in February, 1881. The weather was such that our Secretary was not at our last meeting and our Secretary pro ton having failed to send in his report, I send the above notice.

A. Rice, Pres.

The Nebraska Bee-Keepers' Association will hold their Annual Convention, on the 10th and 11th of February, 1881, at Plattsmouth, Cass Co., Neb. Western lowa bee-keepers are cordially invited to attend.

HIRAM CRAIG. Pres.

EDITOR AND PROPRIETOR.

CHICAGO, ILL., JAN. 12, 1881.

# How to Prepare Bees for Shipping.

When is the best time to ship bees from here to Dakota, and please give directions for preparing them for shipment that far?

J. B. Ellison.

[The best time for shipping that distance would be April, or quite early in May, before the combs are too heavy with brood; but with proper care in preparing them and ordinary usage in handling, they may be shipped at any time with comparative safety, except in quite cold weather.

The first work is to go through your hives and extract about all the uncapped honey, as the least daubing will prove fatal to the bees; then procure a block one inch square, and as long as the hive is wide, in this cut notches and tack in the bottom of the hive, in which to place the frames to keep them steady; now select the new combs and those heavy with broad or sealed honey, secure them well in the frames with stripbinders, and place in the hive; tack the ends of the frames firmly to the rabbets on which they rest; dip the blanket in clean water, lightly wring, fold about 6 thicknesses, and lay on the front ends of the frames. If your hive has no portico, leave off the cover, and instead use wire cloth, nailing on-top of that three 1-inch strips, 2 inches wide—1 across the centre, the others across each end-to insure ventilation when piled on each other. Now tack wire cloth over the entrance, and your bees are ready for shipment to Australia if needs be.

If the hive has a portico, prepare in the same manner as above, except to bore a 115 inch hole in each side of the brood chamber, and also in the cover, which will be used in place of the wire cloth over the frames; the holes to be covered inside and outside with wirecloth, to admit of ventilation. Leave the entrance open full size, but cover the entire portico securely with wirecloth, leaving free access to it from the interior of the hive.

Prepared in this manner, we have shipped full colonies, at all seasons from May 1st till Aug. 10th, to Connecticut, Canada, Pennsylvania, Virginia, South Carolina, Georgia, and many other States, North and South, with perfect success. In August last Mr. Alfred II. Newman shipped a colony, prepared in this manner, to New Zealand, via San Francisco. The trip occupied six weeks by railroad and ocean steamer. Return advices, after a lapse of three months. stated they arrived safely and in good condition, but many of the bees were dead, which were probably old bees. He has an order from New South Wales for two colonies in the spring, which he informs us will be prepared in the same manner.—Ed.]

Sample copies of the Weekly BEE JOURNAL will be sent free to any names that may be sent in. Any one intending to get up a club can have sample copies sent to the persons they desire to interview, by sending the names to this office.

# Compulsory Honesty.

We are frequently in receipt of letters asking for the draft or form of a general law applicable to and prohibitory of, the almost universal adulterative poisoning now so largely practiced. The last number of the American Grocer gives the copy of a bill recently prepared under the auspices of the National Board of Trade, embracing the suggestions of the ablest of the competitive essays received by the Messrs. Thurber, in response to their prizes of \$1,000 offered for the best on the subject. The followmg is a copy of the bill as prepared by

A BILL to Prevent the Adulteration of ood or Drugs.

Be it enacted, &c., That no person or cor-poration shall knowingly transport, or cause to be transported, from the State, district, or territory, in which he resides or does or territory, in which he resides or does business into any other State or territory, or from any foreign country, or other State or territory, into the State or territory in which he resides or does business, for sale or bar-ter, or to be offered for sale or barter, any article of food or drugs adulterated within the meaning of this act, and any person violating the above provision shall be deemed guilty of a misdemeanor, and upon conviction thereof shall be fined not more than fifty dollars for each offense.

than fifty dollars for each offense.

SEC. 2.—That no person shall, within the District of Columbia or in any of the territories, or in any fort, arsenal, dock-yard, or reservation, or other place under the Jurisdiction of the United States, manufacture, offer for sale, or self any article of food or in its which is adulterated within the meaning of this act, and any person violating this provision shall be deemed guilty of a misaemeanor, and upon conviction thereof shall be pumbled by a line not exceeding fitty dollars.

SEC. 3.—If, on examination of any article

SEC. 3.—If, on examination of any article of food or drugs imported from any foreign country, it is found to be adulterated within the meaning of this act, a return to that effect shall be made upon the invoice, and articles so noted shall not be permitted to pass the custom-house or be delivered to the pass the custom-house of be derivered to the consignees, unless on re-examination, as provided for in this act, it shall be found that the said articles are not adulterated.

SEC: 4.—The owner or consignee shall have the privilege of catting at his own ex-

have the privilege of calling at his own expense for a re-examination, and on depositing with the Collector of Customs such sum as he may deem sufficient to defray such expenses it shall be the duty of the Collector of Customs to produce a certificate, under oath from a public analyst, of a caretal analysis of the articles in question; and in case the report by certificate of the analyst shall declare the report of the officer who examined the goods to be erroneous and the said articles to be unadulterated, the said articles shall be returned to the owner or consignee, and passed without reservation on payment of the duties, if any. But in case the officer's return shall be sustained by the analyst the said articles shall remain by the analyst the said articles shall remain by the analyst the said articles shall remain in charge of the Collecter of Custons, to be disposed of in accordance with regulations to be prepared by the National Board of Health and approved by the Secretary of the Treasury: Provided, That the owner of consignee, on payment of charges of storage and other expenses necessarily incurred by the United States, and on giving bond, with sureties satisfactory to the Collector, agreeing to remove said articles from the United States, shall have the privilege of re-exports.

shreties satisfactory to the Cohector, agreeing to remove said articles from the United States, shall have the privilege of re-exporting them at any time within the period of six months after the date of the report of the inspector or public analyst.

SEC, 5.—In order to carry into effect the provisions of this act, the Secretary of the Freasury is hereby authorized to appoint from names submitted to him for that purpose by the National Board of Health one or more suitable qualified persons as special inspectors and as public analysts for adulterated food and drugs at such ports of entry as the Secretary of the Treasury may deem expedient, and it shall be the outy of the National Board of Health to prepare instructions governing the work of such inspectors and analysts, which, when approved by the Secretary of the Treasury, shall govern their action, and that of collectors of customs, in preventing importation from the content of the description of the preventing of the secretary of the freasury.

SEC. 7.—It shall be the duty of every district attorney to whom the Secretary of the National Board of Health or any collector of customs shall report any violation of this act to cause proper proceedings to be commenced and prosecuted without delay for the fines and penalties in such case provided, unless, upon inquity and examination, he shall decide that such proceedings cannot probably be sustained, in which case he shall report the facts to the National Board of Health. And for the expenses incurred and services rendered in all such cases the district attorney shall receive and be paid district attorney shall receive and be paid trom the Treasury such sum as the Secre-tary of the Treasury shall deem just and reasonable, upon the certificate of the judge whom such eases are tried or disposed.

SEC. 8.+An article shall be deemed to be adulterated within the meaning of this Act:

A .- In the case of drugs.

1. If, when sold under or by a name recognized in the United States Pharmacopena, it differs from the standard of strength quality or purity land down therein.

2. It, when sold under or by a name not recognized in the United States Pharmacopona, but which is found in some other pharmacopeda or other standard work on Materia Medica, it differs materially from the standard of strength, quality or purity

and down in such work.

3. It its strength or purity fall below the professed standard under which it is sold.

B.-In the case of food or drink.

If any substance or substances has or have been mixed with it so as to reduce or lower or injuriously affect its quality or

It any inferior or cheaper substance

or substances have been substituted wholly or in part to the article.

3. It any valuable constituent of the article has been wholly or in part abstracted.

It it be an imitation of or be sold

4. If the an inflation of or be soft under the name of another article.

5. If it consists wholly or in part of a diseased or decomposed, or putrid or rotten, animal or vegetable substance whether manufactured or not, or in the case of m.4k.

animal or vegetable substance whether manufactured or not, or in the case of indk, if it is the produce of a diseased animal.

6. If it be colored or coated, or polished or powdered, whereby damage is conceated, or it is made to appear better than it really is, or of greater value.

7. If it contain any added poisonous ingredient, or any ingredient which may render such article injurious to the health of a person consuming it: Provided. That the National Board of Health may, with the approval of the Secretary of the Treasury from time to time declare certain articles of preparations to be exempt from the provisions of this act: AND PROVIDED FURTHER, That the provisions of this act shall not apply to mixtures or compounds recording the same are not injurious to health, and that the articles are distinctly labelled as a mixture, stating the components of the New Street of the New Str

mixture.

SEC. 9.—It shall be the duty of the Na-SEC. 9.—It shall be the duty or me tional Board of Health to prepare and plish from time to time lists of the artic mixtures or compounds declared to be ex empt from the provisions of this act in ac-cordance with the preceding section. The National Board of Health shall also from time to time fix the limits of variability permissable in any article or compound. SEC. 10.—The term "food" as u

used in this act shall include every article used for tood or drink by man. The term "drug" as used in this act shall include all medicines for internal or external use

cines for internal or external use.

SEC. 11.—All the regulations and declarations of the National Board of Health, made under this act from time to time and promulgated, shall be printed in the Statutes-at-large.

SEC. 12.—This act shall take effect ninety days after it shall have become a law.

days after it shall have become a law

We would suggest amending § 1, 2d or cause to be manufactured, sold, or between the words corporation shall. The penalty for violations should be not less than \$50 nor more than \$100, and confiscation—one-half the fine to go to the informer, when collected. The sections should all be modified so as to simplify prosecutions and render more simplify prosecutions and render more customs, in preventing importation from to reign countries of tood or drugs adulterated within the meaning of this act.

Sec. 6.—The National Board of Health shall make, or cause to be made, examination of specimens of food and drugscollected under its, direction in various parts of the country, and shall publish in its weekly bulletin the results of such analyses. If it shall appear from such examination that any of the provisions of this act have been violated, the Secretary of the Board shall at once report the facts to the proper United States district attorney, with a copy of the

results of the analyses duly authenticated appended as a part of § 8 meet with our by the analyst under oath.

SEC. 7.—It shall be the duty of every dis-

A bill should be, in fact will be, introduced in Congress at an early day to reform the outrageous abuses now practiced. Meantime, continue to agitate, Bee-keepers' societies, every society or person who is a producer, every mechanic or person who is a consumer, every merchant or grocer who is a buyer or seller-in fact, every honest person-is interested, and should do all in his power to consummate the much needed reform.

# Plant Sweet Clover.

The following extract is from a recent number of the Indiana Farmer, and it is gratifying that their experience has been so identical with ours, as given on page 361, August, 1880, number of BEE JOURNAL. We believe all bee-keepers will fully concur with everything we have heretotore written in favor of planting for honey pasturage, after givmg the matter a fair and invartial trial. We suggest that it will pay to plant sweet clover in the East where land is valuable, for the reason that it is a perfeetly hardy plant, requiring no great care in the preparation of ground, no special adaptability of soil, no scientific or expensive culture, nor an especially favorable season; harrow in the seed, on a waste spot, wet or dry, clay, sand or gravel, hillside or gully, anywhere, and it will take care of itself. In the West, where land is cheap, it will pay to plant it, for it takes no time from other crops. It will pay to plant it in the North, where the winters are long spring bloom late, and frost early in tall, because it gives a continuous bloom in summer, after white clover and basswood have failed in their nectar secretion; and it will pay to plant it in the South, where the summers are long and the drouths severe, for winter frosts and frequent rains are not necessary to its development. We doubt if there is a locality in America overstocked with bees, that has not in its immediate vicinity enough of non-productive soil to give every bee-keeper a remimerative yield of honey, if properly utilized in the production of honeyyielding plants. To be sure, a little expenditure of time and money would be necessary; but not nearly so much as is expended every year in feeding to prevent starving. More bees die each year from want of honey pasturage, than would doubly pay for the time and expense of providing it. Moreover, the consequent increase of stock would repay all expense incurred. At 25 to 30 cents per pound for the seed, any beekeeper can afford to put in at least one line, by inserting "manufacture, sell, pound for every colony. Try it, and try other plants; try everything.

Some five years ago we received a package of sweet clover (Melliolus alba) seed from Mr. C. F. Muth, Cincinnati. We did not believe at that time that planting for honey would pay. Still we concluded to give the matter a fair test. We scattered seed in several different places, selecting as many different kinds of soil as possible. The sequel proved that there is no soil so poor in which melilot will not grow, and it will thrive under almost any or all circumstances, and in all kinds of weather. We have and in an kinds of weather. We have watched this plant closely for the past three years and we are satisfied that it is one of the very best that we can plant for honey alone. Blooming as it does from the first of July to September, makes it of still greater value, lilling the gam from basewood to fall

hat it is fit for nothing else. will sometimes browse on it early in the spring, otherwise it is not touched by stock. Last season, although the bees eould find nothing else on which to work, the melilot kept them busy, enabling us to continue queen-rearing, and to build up nuclei without cessation, until late in the season. It may be sown at any time; it is biennial; does not bloom but very little the first year, and at the close of the second year dies out root and branch. Some objections are raised, claiming that if it becomes fairly esclaiming that if it becomes fairly established it is a pernicious weed; but, as it dies the second year, root and branch, it is easily gotten rid of if not allowed to go to seed. As an ornament to roadsides it is far superior to dog-fennel or rag-weed. To those who own rough, broken, or waste land, we can well say it will pay you to plant melilot. It yields a delicious honey, equal to, if not superior to white clover, especially as regards the flavor. Four pounds of seed will sow an entire acre, although we would advise sowing it only in waste places, along the roadsides, along creeks, brooks, on hillsides, along railroads, etc.

# Congratulations to the Weekly.

While thousands have approved and praised the Weckly, and congratulated us upon its appearance, we are surprised that there are no more who preferred the old size and shape—those who have spoken of this preference being only about one to a thousand who have signified their approval. The enthusiasm over the birth of the Weekly exceeds our most sanguine expectatations, and it is exceedingly gratifying to know that our efforts to make an acceptable paper are so universally appreciated. To all we return thanks for their generous encouragement. The Weekly starts with very flattering prospects, and is a success from the very first. From the many letters of commendation the attention of the reader is directed to the following:

The initial number of the Weekly Bee Journal has made its appearance. We expected a good paper, and the first number indicates that we shall not be disappointed.

F. N. WILDER.

I am much pleased with the first number of the Weekly Bee Journal. I have long wished for a weekly bee paper. GEO. T. WHEELER.

The Weekly has arrived and like it. As of old it is a model publication. Now get up an Emerson Binder suitable for it and we will not only wish the edit for a liappy New Year-but the Weekly Bee Johrnal a successful year.

JAMES HEDDON.

(We have had a large lot of Binders made especially for the Bee Journal, and will sell them at wholesale rates just to accommodate our patrons. They retail for a dollar, but we will send them to any address postpaid for 85 cents.—ED.]

The Weekly is received. I like it. All will be pleased to know what occurs, as events transpire, rather than thirty days after date.

T. F. BINGHAM.

I liked the Monthly; but I like the Weekly better.
GEO, D. STAATS.

l very much appreciate your change of the Monthly to the Weekly Bee Journal. H. CRIPE.

I like the idea of the Weekly Bee Journal. I want and must have every number. I cannot afford to miss one of them.

W. T. STEWART.

I have received the first number of the Weekly Bee Journal and am much pleased with it. D. L. WHITNEY.

The Weekly Bee Jonrnal is the one thing needed t complete my happiness as a bee-keeper. I cannot do without it, and shall not as long as it is published. Success to the Weckly Bee Journal. H. JONES.

l am very thankful that the Bee Journal is to issue every week: formerly it seemed very long to wait a month for it. So it is with pleasure that I send my subscription. My I colonies of bees are in my celar packed in straw and are in good condition.

CHARLE II. BRADISH.

I am pleased with the appearance of the Weekly Bee Journal. I have the pleasure to hand you the difference between my subscription for the Monthly and the Weekly for the balance of my present time. 11. H. LUTTELL.

Mr. G. H. B. Hooper, editor of the *Dominion Apiarum Boznar*, writes: "The Bee Journal is well worth all it costs, and should be in the hands of every bee-keeper in America, as I hope it will be."

I am very glad we are to have a Weekly Bee Journal. I think it will be a great benefit to bee-keeper in general.

A. D. STOCKING.

I welcome the Weekly Bee Journal, and wish it and its editor much success. W.M. CHRIST.

I have received the first copy of the Weckly Bee Jonrnal. It is just the thing, and is what I have been for years wishing for. I hope it will be a success. J. H. MCRDOCK.

I like the Weekly Bee Journal and think it will a benefit to bee-keepers and hope it will pay the publisher well. I wish it success.

D. LoveJoy.

The publisher of the American Bee Journal, here-tofore published Monthly, now issues that well known and favorite periodical Weekly. It is a benutfully printed 8-page, 4-column paper, and is sent to subscribers at \$2.00 a year.—Fruit Gromer.

lam much pleased at the prospect of obtaining weekly news on the subject of bee-culture.

B. E. MILES.

The Wookly Bee Journal has put in its appearance and I am highly pleased with it. To think we are to see it once a week makes smiling faces it our hoise. I am improving sery slowly from my long sickness and hope soon to be able to send you a short article. G. M. DOOLITTIE.

The Weekly Bee Journal is received. I like it very much, and must have every number for ISSL SAMUEL D. RIEGEL.

SAMUE D. RIEGEL.

I learn enough from the Bee Journal to pay the subscription price four times over. I have now 40 colonies in good condition on the summer stands, but sheltered. Bees did not swarm much during the past season though they increased from 25 to 40 and gave me 1500 fbs. of surplus honey. I wish the Weekly every success.

G. T. SMITH.

You have made a long stride in the furtherance of the seience and nrt of bee-culture by issuing a Weekly Box Journal. I congratulate you and hope it will be as great a betteff to its publisher financially as it is to the bee-keeping fraternity generally. K. CORBETT.

It seems like parting with a friend to give up the familiar face of the old Monthly Bee Journal, that have a made me regular visits for so many years; yet I know that this progressive age demands a journal that will be more frequent in its visit.

LEE EMERICK.

I want the Weekly for ISSI. I am thankful fe which I have learned from the Bee-Journal. In far I owe about all I know about bee-keeping to 1 teachings and wish it success. I have 65 colonies; Langstroth lives in the cellar.

Place me on the list, for the Weekly Bee Journal for !ssl. I know it will be good. You have "hit the nail squarely on the head" that should have been driven long ago, in giving us a Weekly Bee Journal. I wish it prosperity and a host of subscribers.

JOHN W. STERWOLD.

The Bee Journal comes in its new garb; it has greatly assisted me through the trials of the past. May its visits in the future bring good news of increasing prosperity for us bee-keepers.

R. H. WEIR.

I hope the Bee Journal will be an abundant success. I have learned much from it in the past, and confidently expect still more the coming year. Give us all the light and knowledge at your command.

B. S. MILES.

I have been greatly benefitted by the Bee Journal in the past, and expect much profit from it in the future. WM. BEARD.

I am well pleased with the prospect of having the Bee Journal Weekly, and wish it abundant success. JOHN BAXTER.

I like the appearance of the Weekly very much, and think it will be much more satisfactory than a Monthly. I send you seven subscribers for it, and we all wish it and you success.

O. J. HETHERINGTON.

O. J. HETHERINGTON.

I received the first number of the Weekly Bee Journal and am highly pleased with the change from Monthly to Weekly. With me it is one of the indispensables. I have if colonies packed with straw on the summer stands with quilt and chaff cashioral processing of the processing of the processing of the processing with the processing with the processing with the processing of the processing of the processing of the processing with the processing of the process

The Weekly Bee Journal is received and I am well pleased it. I should teel lonesome without the Journal, and wish you every success. HENRY S. LEE.

I am very glad to see the Bee Journal in its new form. This step indicates the progress of apiculture, with which the Journal is keeping abreast. A. B. WEED,

I like the change to the Weekly very much. Success to you. E. R. WRIGHT.

Send me the Weekly. I wish you great success with it. I am quite sure it will be a success financially S. C. Dodge.

have received the first number of the Weekly se Journal and like it first-rate. GEO, DRURY,

lam pleased with your new departure in starting a Weekly edition of the Journal. I have not been a reader of the Journal for the past year but will now renew my acquainlunce with an old friend whose pages will greet me every week.

J. H. MARTIN.

I am very much pleased with the Weekly Bee Journal, and would not think of doing without it, and I will find time after a while to write some more articles for it.

M. Mahin, D. D.

There was only one thing lacking in the American Bee Journal and now even that cannot be said of it, for we are to have our beloved Bee Journal four times where hedre we had it only once. It is a great advance in apiculture when there is a demand for a good Bee Journal once a week. The weather has been very cold for the past week, thermometer 10° to 25° below. It will go hard with bees that are not protected.

We have to ask the indulgence of our correspondents. Notwithstanding we have increased the capacity of the BEE JOURNAL to a Weekly, still there is such a quantity of matter sent in that we can only give a tithe part of it this week-but we will give all a chance as fast as possible. The enthusiasm with which the Weekly is greeted, exceeds our most sanguine expectations.

Those who have subscribed for the Monthly or Semi-monthly, and may want to change for the Weekly, can do so at any time by paying the difference.

ES Please examine the date after your name on the wrapper label of this JOURNAL and see that proper credit is given. Such is often a sufficient receipt, now that the JOURNAL comes weekly. In the great rush of the past week or two, some mistake may have occurred which we shall be most happy to correct, if our attention is called to it.

Our stock of No. 1 having been exhausted-we have not been able to send it to many hundreds of names sent in for that purpose. We send this No. in its stead.

The Indiana State Bee-Keepers' Association will hold its annual Convention in Indianapolis, January 13th and 14th. The Convention will be held in the State Agricultural rooms, corner Tennessee and Market Streets. Tennessee and Market Streets, Reduced rates have been secured at several first-class hotels. Many interesting papers will be read on the different subjects pertaining to the science of apiculture. Samples of the latest improved implements used in connection with modern bee-culture will be on exhibition.

FRANK L. DOUGHERTY, Sec.

# GLEANINGS.

Novice reports his lunch room a decided success. It is supplied with all that heart can wish for, including luscious Florida oranges.

KE Novice gives the following very kind notice of the Weekly:

For the first time since the world began, we are to have a Weekly Bee Journal, and I presume it is in the hands of many of you by the time this reaches you. The first number makes a very creditable appearance, and as it will be quite a task for friend Newman to get up such a one every week, shall we not turn in and give him a lift, in the way of subscrip-tions? If 1 am correct, a sample copy will be mailed n application.—Gleanings in Bee Culture.

Imported Queens,—Mr. G. M. Doolittle, is reviewing Novice's A B C book, and on this subject says: "I have had three daughters of imported queens from as many breeders, and none of them compared with the stock I had taken pains to breed for honey. With the majority of apiarists, probably, your remarks are correct; but we have a few breeders whose queens are far ahead of a promisenous importation from Italyat least, such is my opinion. Five hundred dollars would not hire me to breed all my queens from an imported mother, and let my present stock go

Fire Weed is reported by E. Tarr to the greatest honey-producer down in laine. It grows from 4 to 7 feet high, Maine. It grows from 4 to 7 feet high and commences to bloom about Aug. 1 give white honey of fine flavor, and r. T. reports thousands of acresthere, and the few bees in that locality, therein revel with delight.

Perforated Separators.—J. C. Carpenter has gotten up a hand machine for perforating separators. He says it will perforate fin or paper rapidly, and costs but \$5.00. It makes holes three-eighths of an inch indiameter and three-eighths of an inch apart.

# BRITISH BEE JOURNAL.

J. S. Wood copies from the travels of Edward D. Clark, LL.D., the following items on Cyprus and Hymettus bees and

is only as a means of an additional tax. The manner, however, in which the honey is collected is so curious, and so worthy of imitation, that it ments a particular description. The contrivworthy of imitation, that it ments a particular description. The contrivance is very simple, and was doubtless suggested by the more ancient/custom still used in the Crimea, of harboring bees in cylinders made of the bark of trees. They build up a wall formed entirely of earthen cylinders, each about three feet in length, placed one above the other horizontally, and closed at their extremities with mortar. This at their extremities with mortar. wall is then covered with a shed, and upwards of one hundred colonies may thus be maintained within a very small compass.

rom this Monastery (Saliani) it is practicable to ride the whole way to the summit of Hymettus, but we preferred walking, that we might the more leisurely examine every object, and collect the few plants in flower at this late season of the year. We saw partridges in great abundance, and bees in all parts great abundance, and bees in all parts of the mountain, not only at the monastery, where a regular apiary is kept, but also in such numbers dispersed and feeding about the higher parts of Hymettus, that the primeval breed may still exist among the numerous wild colonies which inhabit the hollow trees and elefts of the rocks.

and elefts of the rocks.

Their favorite food, the wild Thyme (Thymus Serphyllum), in almost every variety, grows abundantly upon the mountain together with Salvia pomifera and Salvia verbascum, and to this circumstance may be owing the very heating quality of the honey of Hymettus.

The pawerful aromatic exhalation of these plants fills the air with a spicy oder; indeed, this scented atmosphere is very striking characteristic of Greece

is very striking characteristic of Greece and of its islands, but it peculiarly distinguishes the mountains of Attica.

# BEE-KEEPERS' MAGAZINE.

Test of Adulteration. - Professor Hasbrouck gives the following test of purity for honey: "Honey is very dif-ferent from commercial glucose. It is a mixture in very nearly equal parts of dextrose and laconlose. The dextrose is the part that 'candies,' is the same kind of sugar as that which is found third. arm of sugar as that which is found dried in raisins, and is about one-third as sweet as cane sugar. The lacloulose will not candy, and is sweeter than cane sugar. Glucose made from starch is a mixture generally of one part dextrose and three parts dextrine—a gummy substance used for stiffening calicoes, substance used for stiffening calicoes, and for gunning the backs of postage stamps. Dextrine is never found in pure honey. Now the test of dextrine is the solution of sub-acetate of lead, or Goulard's water, which can be found at any drug store. This precipitates the dextrine in any mixture as a thick white curd, which remains floating in the liquid. The same solution put into honey does not change its color. This simple test is very striking, and always noney does not change its color. In a simple test is very striking, and always reliable. The glucose formerly manufactured contained foreign matter gathered in the process of making, by which it could be easily detected; but the specimens I have seen recently contained in the fitter that the specimens I have seen recently contained. the specimens t have seen recently contained so little of these that they could be demonstrated only by the practical chemist. The way on which we rely to distinguish honey from its adulterants is by the polariscope, with which we can tell the difference between honey and grape sugar, and cone sugar, and glucose, as plainly as one can distinguish gold and iron, by the unaided eye.

# JOURNAL OF HORTICULTURE.

Bees in Ireland.—It has been stated so often that 1879 was disastrous among so often that 1879 was disastrous among bees that I need hardly endose it as regards Ireland. Rain and wind prevailed all the honey season here; but for three or four seasons it has been so impropitious for honey gathering that nearly all the old apiarists have been discouraged. Ifed the bees abundantly in autumn, winter and spring, with syrup made from 4 lbs, of loaf sugar, to a court of water one snoanfal of vinehoney:

In these little cottages we found very large a quart of water, one spoonful of vine-direction of the sign of the large establishments of bees, but all the lioney thus made is demanded by the loney thus made is demanded by the Governor: so that keeping these insects of sticks.

# Conventions.

# Tuscarawas and Muskingum, O.

The Tuse rawas and Muskingum Valley Ree-Keepers Convention met at Newcomerstown O on Wednesday, Oct. 6, at 1 p.m. President I. B. Wolfe being absent. Vice President Rev. W. Ballentine, of Muskingum, was called to the chair. After reading was called to the chair. After reading and approving the minutes of the last meeting, the following questions pro-posed for discussion were taken up. The cells in broad combs by constant

The cells in broad coints by constant of the use become small, does this reduce the size of the bee? This question was opened by Ar. A. B. Thompson and followed by A. A. Fradenberg and Rev. W. Ballentine. After being ably discussed it was referred to A. A. Fradensed it was referred to A. A. Fradensed.

enssed if was referred to A. A. Fraden-berg for consideration at next meeting. Do bees make honey? The opinion of the Convention was that honey was a natural secretion of the flowers, and that bees did not make honey but gathered it from the flowers.

gathered if from the flowers.

What is the best method of wintering bees? A. B. Thompson's method of wintering was in chall-packed hives on summer stands. Mr. J. A. Bucklew's method was to crowd the bees in the center of the hive by means of division. boards, and then packing at each side of the bees with loose chaff, also filling the upper story with chaff. The Convention after considering the different methods of wintering bees gave preference to wintering in chaff-packed hives

on summer stands.

The By-Laws were read and six new members received. Adjourned till 9

# MORNING SESSION.

In the absence of the chairman protom., Vice President A. A. Fradenberg occupied the chair:

Do you work for extracted or comb

honey, and from which do you realize

This question was one of some importance, and was ably discussed. On account of a lack of a home market to extracted honey bee-keepers had almost entirely worked for comb honey as there was a ready sale for all that had been produced.

R. L. Shoemaker strongly account of the extracted honey, advising bee-keepers to use the extractor, and to place it upon subset in neat and attractive shape. with a guaranty that it was pure, and, had been just the same as consumers had been getting in comb honey, only they would get it cheaper. The opinion of the get it cheaper. The opinion of the Convention was that more honey could be taken with the extractor than in the demand for extracted honey it paid best in the comb.

Can fertilization in confinement be made a success if so, how? It was answered that it was not as yet a suc-

cess, and may never be,
Introducing queens? A. A. Fraden-Introducing queens? A.A. Fraden-berg practiced the Betsinger plan and was generally successful. Mr. Nico-demus used a wire-cloth cage, of his own make, and introduced by Novice's method. J. A. Bucklew removed the queen to be superseded and placed the new queen in a wire cloth cage, between two of the brood combs for 4s hours : at the broad combs for 48 hours; at the end of that time he removed one of the stoppers from the eage and in its place put a plug of comb honey and allowed the bees to liberate the queen themselves when all was quiet.

How shall we feed bees that lack win ter stores—what and when to feed?—It was answered that the time to feed was m August and September, and to use some one of the bee feeders now make. some one of the neer receives now mouse, on to take a glass fruit jur, fill it, tie a a cloth over the mouth of the jur and invertit over the cluster of bees, and in that way a gallon of feed could be and September in order that the bees may have time to cap it over before cold weather. For feed, use however best coffee A significant against sympot

J. A. Bucklew, Clarks, O : R. L. shoemaker. Newcomerstown, O., and A.J. Wardell, of Uhrichsville, O., were chosen as a committee to arrange programme.

On motion the Convention adjourned to meet at Cambridge, Ohio, on the first Wednesday in May, 1881.

A. B. Thompson exhibited Peet's com-A.B. Thompson extraorer experience of the bined shipping and introducing queen cages. J. A. Bucklew exhibited sample copies of the four leading bee papers of the United States. The Convention tendered their thanks to the citizens of Newcomerstown for the use of their

# . . - . . Michigan State Convention.

The Michigan State Convention of bee-keepers met at Lausing, on Dec. 8, 1880. As usualit was well attended and harmonious.

Imitation honey and sugar were condemned and a committee, consisting of the State Board of Health, was ap-pointed to bring the subject of adultera-tion before the State Legislature at once. A committee was also appointed to

bring the question of foul broad before the Legislature with a view to prevent its spread and assist in its eradication. Foul-brood was reported to have existed around Battle Creek last summer, to some extent, but it is now believed to be eradicated, except in one small apiary, consisting of 6 colonies, in West Leroy. consisting of 6 colonies, in West Lefty. The owner refused to destroy it, even when Mr. Salisbury and others offered to give him (the owner) healthy colonies in place of his sick ones, without money and without price. It is this case of selfish disregard to the interests of others without excuse or palliation that induced our Convention to bring the matter before the Legislature hope to have a law similar to Utah's on the foul brood matter, and if it works as well as our law relating to Yellows in peach trees in this State, which was brought forward by the Michigan Pomological Association, this action of our Association will be regarded as of great value to bee-keepers everywhere.

Parties receiving queens in cages were urged to put them in other cages known to be clean, before putting them in their hives, and to destroy the bees and hoil the cages in which queens were received from other apirries, as a means of avoiding the risk of obtaining foul brood in the purchase of queens from other apiaries.

congratulatory letters and Many congratulatory letters and essays were received and read, and votes of thanks were unanimously passed to the writers; among them were the following:

wish to call the attention of the Michigan State Association to the importance of thoroughly organizing your portainer of thoroughly organizing your State by counties, into bee-keepers' soci-eties. There are many who will attend County Associations that will not attend the State or District Societies. The attendance at our meetings is mostly local and therefore the necessity of county organizations; not that I would county organizations; not that I would do away with the State and District Associations, but build them up by spreading the knowledge of bee-culture among the farmers and that class of bee-keepers who are still ignorant of the inventions and discoveries in admiriting might have the seconds. scientific apiculture. As all the schools of learning in various sciences have adopted titles to distinguish them from other professions, I suggest that you bring the matter before your Association for investigation, &c., of adopting tion for investigation, &c. of adopting a title for bee-keepers. May your light shine more, and more, until ignorance and superstition will be vanished from our land and the light of scientific bre-culture shall be seen and appreciated by all the world. We are having very cold weather for this climate, the ther about the consistency of honey.

Mr. A. A. Fradenberg by the aid of a ber. That is something new with us hive favored the Convention with an explanation of D. A. Jones, a Canadian berish this winter. We winter on sumbee-keeper's method of working bees as a many colors of bees will be be kind of ceinar will. That is not given up bee keeping, and doubtless, like the various kinds of probably never shall entirely. To what hives we use, be a subject tor difference extent 1 shall continue it will depend of opinion and debate; but with the chiefly upon whether or not it will consent a constraint of ceinar will. Indeed not given up bee keeping, and doubtless, like the various kinds of probably never shall entirely. To what hives we use, be a subject tor difference extent 1 shall continue it will depend of opinion and debate; but with the chiefly upon whether or not it will consend the constant of ceinar will.

explained by Mr. Jones at the National tion, and many of us had not put our modation of 50 colonies can be easily Convention, at Cincinnati, O.

Cambridge, Gurnsey Co., Ohio, was chosen as the place to the next meets chosen as the place to the next meets will not fail to appoint delegates to the should be about 10 feet each way, with wan nor any to appoint delegates to the National Association. Permit me to ask your Society for its co-operation in making the National Association a power for good and that it may prosper and prove a blessing to the bee-keepers not only North America, but the world.

orld. N. P. ALLEN.
Pres. National Association.
Smith's Grove, Kv.

It is very difficult to write anything tresh and new upon the subject pertaining to apiculture, and I besitate to begin; but I like the friendly way you brethren in the far north have of calling upon your southern friends to join you in your onward stride towards improvement in our pet science of apiculture. I was talking with a gentleman from your State yesterday, and he expressed his surprise at the thrift of our people. and the friendly reception tendered to any and all gentlemen from the north any and all gentiemen from the north by the southern people. If any one of you have any fears, from political rea-sons, to come among us, tell him or them, one and all, that they are deluded. for our hospitality is as broad as our fields.

S. C. Dodger.

Chattanooga, Tenn., Nov. 23, 1880.

Several other letters were received by the secretary too late for the Convention, among which were one each from 11. A. Burch and O. J. Hetherington.

The following essay, by Mrs. L. B.

# Cellar vs. Out-Door Wintering.

Lassume that the three following conditions are essential to the best success in wintering bees, in-door or ont, name-ly, perfect quiet, total darkness, and pure air of uniform temperature; and be under control by the apiarist.

For the present purpose we will consider the most approved chaff hive on his the one hand and the best arranged cel-will lar on the other in the attempt to prove that the indispensable conditions re-ferred to may be more nearly approximated in the cellar than out of doors

The first condition in the order is perfect quiet. That this cannot be so nearly attained out of doors seems evident when we consider that there are six months of exposure to storms of rain, hailandsnow, with the accompanying changes of temperature, which, despite the double-wall and packing, must have a disturbing effect upon the must have a distincing effect upon the sensitive cluster within. Furthermore, unless the apiary be seemely fenced, disturbances may arise from swine and muruly cattle, or possibly from human

depredators.

The obstacles in the way of the second condition, namely, total darkness, are not so great, but do in a degree exist.

The entrance left open for air will also admit light, and although but a taint ray, may be sufficient to tempt them to flight when a disturbance occurred. cours, at a time when exposure would be fatal. thus gradually depleting the colony. In the cellar specially prepared for them there is not as I can show, the slightest obstacle in the way of securtotal darkness

ing total darkness.

The third condition nume air of uni-The finite condition—pure air of uniform temperature—although last in the order, is, I am sure, first in importance, This secured, and the problem of wintering bees has been practically solved. Thanges of temperature, if telt, produce lisquiet. That a colony of bees with disquiet. disquiet. That a colony of bees with all their packing and other absorbents can be as thoroughly protected from these changes when the muncury stands on one day at 35° above zero and on another at 10° below, as they could in a dry repository, with a range of temperature not to exceed 10°, does not seem possible. I believe that this condition can be better secured in the cellar them by any method of our door. hr than by any method of out door packing that has yet come under my

observation.

Precisely the best kind of cellar will doubtless, like the various kinds of hives we use, be a subject tor difference

constructed from a portion of any ordinary vegetable cellar. It square, it should be about 10 feet each way, with should be about to reet each way, with double plastered wall with air space, plastered overhead, and made imperplastered overhead, and made impervious to frost. If the floor is not dry, have and cement it. The door should be tight fitting. A window is not necessary for the bees. I should by no means omit it, however, as it makes the room a treasure, worth all its cost, for a milk room or pantry in the heat of summer. The window should be doublesummer. The window should be double-glassed and provided with a close-fitting shutter that will exclude every ray of light when desired. The room thus ar-ranged is complete, and its ventilation ranged is complete, and its ventuation is as simple and inexpensive as its conconstruction. Connect one side of the room, near the floor, in the most convenient way with the chimney in most constant use, by means of a stove-pipe. From the opposite side of the room. rion the opposite side of the room, midway between floor and ceiling, run a common five or six-inch drain tileat any convenient angle, well below the frost-about 50 feet in length, bringing it to the surface by a right angle, and covering it in such a way as to exclude leaves and other substances while allowing a free ingress of air. If you close the door you will perceive a steady. quiet flow of tempered air through the room. The draft can be regulated by a room. The draft can be regulated by a damper in the stove-pipe. In extremely cold weather the air should flow through the tile very slowly, that it may be brought to the temperature of the earth surrounding it.

In a cellar similar to this I have kept In a cellar similar to this I have kept bees for the last four years without the loss of a colony. We estimated the cost of the cellar at \$10.—1 am informed that a chaff hive like Shuck's cannot be manufactured for less than \$4.00, a price just double that of a single-wall hive. For 50 hives of each kind the difference in the color of the color of the color of the color. in price would amount to \$100. Deduct \$40 for the cellar and we have a balance of \$60 in favor of cellar wintering.

Another item in its favor is that a hive securely housed one half the year will last much longer than one that is constantly exposed. A common objection made to cellar-wintering is the labor of carrying the hives into and out of it, and perhaps doubling the opera-

tion by giving them a mid-winter flight. We paid a man 50 cents for putting 25 We paid a man 50 cents for putting 25 colonies into the cellar of course under our supervision). At this rate the cost for the season of moving 50 colonies would amount to \$100. Will that sum cover the cost of packing 50 chaff hives? A superiority claimed for the double-wall hive is that it will better protect the bees from the heat of the sun. Will it not also retain the heat generated within hy broad-recript horage than the

within by brood-rearing longer than the single hive the walls of which come immediate contact with the cool night air? For summer protection we think we have something that has all the advantages with some of the disadvantages of a chaff hive, and at a slight cost. It is an awning made of canvas, about three feet wide by four feet long. furnished with slats at each end, and with four screw hooks, one at each corner, which tasten to four stakes. The canvas is prevented from resting on the top of the hive by a strip of board three tour inches wide, which serves as a t of ridge-pole. Under the awning sort of ridge-pole. Under the awning the breezes play, and the hive is shaded and fanned when desirable, and when it is not it can be laid aside. In the hot-test weather, with our hives and awnings, the bees do not cluster out except when ventilation has been neglected, The awning it must be remembered, is a protection to the hive from weatherbeating as well as a somer of comfort

I am now done with the subject under special consideration, but would like to add a few words, personal and otherwise, upon bee-keeping for women. Within the last two or three years I have heard from various sources that I was about to give up bee-keeping, and the about to give up necesceping, and the inference was invariably that it was no longer profitable. The facts are that I have not given up beckeeping, and probably never shall entirely. To what extent I shall continue it will depend which many whether or not it will continue in the state. THE AMERICAN BEE JOURNAL.

To nearly all women, at some time or other, will come the query. What can I do for self support in case a possible I do for self support in case a possible emergency makes it necessary?" It came to me eight years ago, and I thought I would see what there was in bec-keeping. Every year up to the present has found me amply satisfied with the returns for my time and labor, but has not proved that I could rely upon it for self support. Whether I could or not I was anxions to demonstrate by actual experience, for the benefit of other women as well as my own, for although a failure on my part own, for although a failure on my part would by no means signify failure for others, it would most certainly prove that what 1 could do others also could do. I wished to see how many colonies I alone could do the work for, and also I alone could do the work for, and also how many more I could have sepervision of and make profitable. This I have not been able to accomplish, and perhaps never shall. Duties that cannot be laid aside would now make the attempt impossible. It may be that attempt impossible. It may be that other women have made the experiment and brought it to a successful termination. I hope so, but do not know. There are many of us, however, who have made it profitable in proportion to the extent to which we have engaged in it. All vocations are now open to woman, and it is a matter of little or no surprise to see her try her hand at any of them; while from the necessities existing we are glad it is so, yet there are multitudes of women who rejoice at opportunities toward self-support that do not lead away from home—"the woman's king-

Officers elected for the ensuing year Cook, Lansing: Vice Prisident, A. J. A. Robinson, Battle Creek; A. W. Colm, Belleview; Treasurer, L. B. Baker, Lansing; Secretary, T. F. Bingham,

Otsego.

Battle Creek, will be the next place of meeting. On account of being extremely busy now I am not able to write out the official report of proceedings, but hope to be able to furnish them soon.

T. F. BINGNAM, Scc.

(Several essays were read which have been omitted from this report, but will be published hereafter.-ED.]

# Letter Drawer.

Disturbing Bees in Winter.-Will it do Disturbing Bees in Winter.—Will It do to disturb bees in winter by putting on mats? I have some mats on that are made from old quilts; they will not absorb the moisture, but let it freeze on top of the frames. What shall I do with them? N. W. WILLIAMS. North Union, O.

[No; if cold enough to chill them. Let them alone till warm enough to fly, then change the quilts.—ED.]

Adulteration.—The Weekly AMERICAN BEE JOURNAL is at hand: I am well pleased with it, particularly with your article on adulteration. Continue your article on adulteration. Continue to sound the trumpet of warning. Let our brother bee-keepers read and reread. All such articles should be taken to our county papers and copied into them, so that every reader in the land will become posted and a general cry will go up to our legislators for more stringent laws in the matter. The first step is to adjust our meanly against stringent laws in the matter. The first step is to educate our people against adulteration. Is there any better chance to do this than through our local papers?

E. Liston.

Virgil City, Mo., Dec. 27, 1880.

The Outlook.—The present outlook for bees is not at all encouraging in this section. Many have left their bees on summer stands wholly unprotected, which means, live if you can. The bees went into winter-quarters much less in numbers per calony than usual; many went info winter-quarters much less in numbers per colony than usual: many more dying late in the fall and early winter than usual, leaving bees gen-erally in poor condition for the long winter. I much like the appearance of the Weekly BEE JOURNAL and I heartily wish it a happy new year. Byron, Ill., Jan. 3, 1881. A. RICE.

Wintering Bees. Thave just received the Weekly BEE JOURNAL with which I am much pleased. I would send you the money for it now but quite a number of us will send for it in a short time, which is much easier than sending for one copy at a time. We are using the Golden bee hive in this county; it is a success. I cannot afford to do without the American Bee Journal for three times its cost. As to the wintering of bees, all that the Journal, contains on this subject is worth nothing to tains on this subject is worth nothing to us, as our bees winter themselves. They go into winter-quarters with plenty of honey and are therefore, prepared to take care of themselves. I pared to take care of themselves. I procured a Henderson queen last summer; she is a real beauty. I am going to supply my apiary with queens from her next year. Please send me the Weekly and the money will be sent in a short time. short time. Biardtown, Texas.

[Certainly: if requested to do so, we cheerfully send on the BEE JOURNAL and give a little time. In fact, we much prefer to do so, rather than to take the name from our "List" and then substitute it, a short time afterwards. All we want to know is—that it is desired to be continued, and hence give this general notice.

If any one desires the Weekly Bee JOURNAL and it is not convenient to pay for a year at once, they can send \$1.00 for 6 months, or 50 cents for 3 months. It costs no more in that way, except the postage. For all fractions of a dollar send one, two or three-cent postage stamps.—Ep.]

Losses in Winter Feared, - I have Losses in Winter Feared.—1 have about 50 colonies of bees; they did well here in the early part of the season, but not so, in the latter part. I fear heavy losses in bees before spring, the weather is so rigorous. I wish the Weekly BEE JOURNAL all possible success.

JAMES A. BUCK.

Washington, D. C.

Washington, D. C.

Prospect for next Season.—Bees in our locality done poorly this season. I have 125 colonies all in good condition in the Mitchell hive, all packed with clover chaff, on their summer stands. We look for a big thing in the way of honey next year. The white clover is abundant. Success to the JOURNAL in its new form.

S. M. OLDHAM. Reynoldsburg, O., Dec. 28, 1880.

Good Crop.—The first number of the Weekly BEE JOURNAL to hand. I am well pleased with it. My bees have done very well this year. I obtained 40 lbs. of honey from a second swarm, all in 1-lb. sections, and have plenty to winter on. Bees are well packed out-doors. The weather is very cold; 10° below zero here now.

10. P. Campbell.

Park Hill, Ont., Dec. 30, 1880.

Cold Weather in Kentucky.—The ex-extremely cold weather of November has killed a good many weak colonies, and the strong ones have suffered more or less. But few bees here are prepared thoroughly enough to endure such cold weather, and I fear many will perish before spring comes. N. P. Allen.
Smith's Grove, Ky., Dec. 13, 1880.

Much Needed.—I am greatly pleased that our editor has concluded to give us a weekly BEE JOURNAL. The want of a weekly BEE JOURNAL. The want of such an aid to our labors was much felt during the honey season, when timely articles from our best writers were eagerly looked for and gladly perused as soon as received.

WM. S. BARCLAY.

Beaver, Pa., Dec. 20, 1880.

Bees Need a Fly.—My bees have all been housed for some time—they need a fly now. Heavy losses in bees are reported among those who use box or single-walled hives.

M. G. REYNOLDS.
Williamsburg, Ind., Dec. 21, 1880.

Bees in Scotland. As far as I can learn from various districts in Scotland, bees are all in excellent condition; I bees are all in excellent condition; I hope they will continue so till spring. The last heather honey harvest here was the best for inwards of 50 years. The weather has been storming for the past 10 days, but more settled and mild to-day.

JOHN D. HUTCHISON.

Glasgow, Scotland, Dec. 14, 1880.

Space under Combs.—I am well pleased with the first number of the Weekly BEE JOURNAL. My honey crop for this season was over 5,600 lbs.; average over 50 lbs. per colony. I had more honey this season than last. My experience this fall is like Mr. Wm. Camm. I think there should be quite a space under the combs in winter.

BENJ. FRANKLIN.

FRANKLIN. Benj. Franklit Franklinton, N. Y., Dec. 27, 1880.

Not a Pound of Honey.—Another season is past and our labors are closed in the apiary for 1886; and what is the rethe aparry for 1886; and what is the result; simply a failure, not a pound of surplus honey from 23 colonies; being the poorest season for honey since I have kept bees; but I am not discouraged. I hope for better things next year. I must have the Weekly BEE JOURNAL, cannot afford to lose a number, even if I did not get any honey last year.

H. D. EDWAEDS. H. D. EDWARDS. last year. Delhi, Ill.

Hard Winter for Bees.—I have sold my comb honey in Buffalo at 18c. per pound. My 60 colonies are packed in plainer shavings and are in good condition so far. A man reported to me to-day 9 colonies dead out of 90—frozen to-day 2 colonies dead out of 90—frozen he says. It will be a hard winter for bees unprotected. I am glad the Jour-NAL is to be a Weekly hereafter. I wish it success. JAMES S. LORD.

Linden, N. Y.

Good Yield.—I have 50 colonies of hybrids, and have sold \$185, worth of honey at 12½ cents per pound, and have consumed and given away some \$60, worth more. Put me down for the Weekly BEE JOURNAL.

Weston, Texas. A. D. BUCKLY.

Comb Foundation.—" While the Dunham foundation I believe is sold for the hain foundation t believe is sold for the same price as the other sorts, it is really worth more, from the fact that it is more difficult to make." Twice have we read the above in the BER JOURNAL. May we add: and for the other reason that it does not sag, and entirely does away with any use for wax sheets, pressed on strips of wood, paper, wires, etc. Our friends will excuse us we Our friends will excuse us we why mumble the truth as the

donkey does a thistle, cautiously?

Carson City, Mich. HIRAM ROOP.

Had a Fly.-My bees have had a good if a a riy.—My bees have had a good fly the last two days, the first since the end of October; they are yet on the summer stands. Most of them are in double-walled hives. I have about 40 colonies in Langstroth hives, and an undecided whether to put them in the coller or yet. Light two, thirds in cellur. ellar or not. I lost two-thirds in cellar HIRAM CRAIG.

Fort Calhoun, Neb., Dec. 13, 1880. ---

The Northeastern Bee-keepers' Association will hold their Eleventh Annual Convention, in the Common Conneil chamber, at Utuca, N. Y., on the 2d, 3d and 4th days of February, 18sl. The Executive Committee are determined to maintain the high standing the Association has justly gained in the past, and propose to out-do all former efforts at the commy Convention. Essays or addresses are expected from Capt. W. F. Williams: Prof. J. Hasbronck; Mrs. Frances Dunham; Janues Heddon; Chas. Dadant; H. A. Burch; Jon Y. Detwier; C. P. Dadant; A. G. Thurber; W. A. House; A. J. King; Julius Hoffman and others.

A gold medal will be awarded for best essays, on the following subjects: "The different races of beand their crosses." "Wintering bees," "Marketing honey," "How can we make the aplary the most profitable?"

honey.<sup>9</sup> "How can we make the aplary the most profitable?"

# Books for Bee-Keepers.

Cook's Manual of the Apiary,—Entirely rewritten, greatly enlarged and elegantly illustrated, and is fully up with the times on every conceivable subject that interests the apiarist. It is not only instructive, but intensely interesting and thoroughly practical. The book is a masterly production, and one that no bee-keeper, however limited bis menus, can afford to do without. Cloth, \$1.25; paper covers, \$1.00, postpaid. Per dozen, by express, cloth, \$12; paper, \$9.50.

Quinby's New Ree-Keeping, by L. C. Root.— The author has treated the subject of bee-keeping in a manner that cannot fail to interest all. Its style is plain and forcible, making all its readers sensible of the fact that the author is really the master of the subject. Price, 81.50.

Novice's A B Cof Bee-Culture, by A. I. Root. This embraces "everything pertaining to the care of the honey-bee," and is valuable to beginners and those more advanced. Cloth, \$1,25; paper, \$1.00.

King's Bec-Keepers' Text-Rook, by A. J. King.—This edition is revised and brought down to the present time. Cloth, \$1.00; paper, 75c.

Laugstroth on the Hive and Honey Bee This is a standard scientific work. Price, \$2.00.

Blessed Bees, by John Allen.—A romance of bee-keeping, full of practical information and con-tagions enthus msm. Cloth, \$1.00.

Rec-Culture; or Successful Management of the Apinry, by Thomas G. Newman.—This pamplet outbrace of the Apinry and the Apinry a

cents, postpind, or road per dozen.

Food Adulteration: What we cat and should not cat. This book should be in every family, where it ought to create a sentiment against the adulteration of food products, and demand a law to protect consumers against the many bealth-destroying adulterations offered as food. 20 pages. Paper, 50c.

The Balerzon Theory; -presents the fundamental principles of bee-culture, and furnishes a condensed statement of the facts and arguments by which they are demonstrated. Price, 15 cents.

which they are demonstrated. Price, 15 cents.

Honey, as Food and Mediteine, by Thomas G. Newman.—This is a pamphlet of 24 pages, discoursing apon the Ancient History of Bees and Honey; the nature, quality, sources, and preparation of Honey for the Market; Honey as an article of tood, giving recipes for making Honey Cakes, Cookies, Puddings, Foam, Wines, &c.; and Honey as Medicine, followed by many useful Beches. It is intended for consumers, and should be scattered by thousands all over the country, and thus useful recently a demand for honey. Published in English and German. Price for either cilition, 6c; per dozen, 50c.

Wintering Bees.—This pamphlet contains all the Prize Essuys on this important subject, that were read before the Centennial Bee-Keepers' Associa-tion. The Prize-\$25 in gold—was awarded to Prof. Cook's Essay, which is given in full. Price, 10c.

Hees and their Management. This pamphlet was issued by the Indian Bee Company, and has had a large creduation. The price has been reduced from 20 cents to 10 cents.

The 111ve I Use-Being a description of the hive used by G. M. Doolittle. Price, 5c.

Kendall's Horse Book No book can be more useful to horse owners. It has 35 encrayings illustrating positions of sick hoses, and trents all diseases in a plant and comprehensive manner. It has a large number of good recipes, it able of doses, and much other valuable horse intermation. Paper, 25c.

Chicken Cholern, by A. J. Hill, -A treatise on its canse, symptoms and cure. Price, 25c.

Moore's Universal Assistant contains information on every concelvable subject, as well as receipts for almost everything that could be desired. We don't if any one could be induced to do without it, after having spent a few hours in looking it through. It contains 480 pages, and 500 engravings. Cloth, \$2.50.

Ropp's Easy Calculator.—These are bandy tables for all kinds of merchandise and interest. It is really a lightning calculator, nicely bound, with slate and packet for papers. In eloth, 81.00; Morocco, \$1.50. Cheap edition, without slate, 50c.

# The Stingless Bees of South America.

REV. L. JOHNSON.

I received, a few days ago, a copy of I received, a few days ago, a copy of Mr. Hawley's circular upon the stingless bee, mentioned in the AMERICAN BEE JOURNAL of January 5th. As I suppose thousands of these circulars are distributed among the bee-keepers of America, many of whom are yet inexperienced, it is well to notice this new advocate for public favor.

hives against their depredations, except the fear of being stung. Let it but once be generally known that our bees cannot sting, and our honey will be pilferred as constantly as our mellons and fruit. A big dog, and shot-gun, and a faithful guard must then occupy the place of the smoker, bee-vail and guantlets. As for myself 1 think the latter preferable and decidedly the cheapest. While we all want the best bee the world affords, we should not, increase our present difficulties by grasping at the near shadow of these untried rovers of the tangled wilds of Brazil.

Walton, Ky., Jan. 3, 1881.

For the American Bee Journal,

# Rocky Mountain Bee Plant.

D. S. GRIMES.

Some of the descriptions of this plant—Chome integrifolia—hardly do it justice as a honey-producer. It grows to the height of four or five feet, with hard woody fibers like mustard, often measuring more than one inch in diameter. The seeds are borne in pods much the size and appearance of the black mustard. It blooms early in the spring, and continues in bloom until frost. As the season advances the spikes of the beautiful flowers continue to grow in length, with seeds and flowers in all stages of growth from the full pods to the new opening bloom. The leaves throw off a very offensive odor when handled.

As a honey-producing plant it is second to no other. In our apiary we have forty colonies of bees, and although we are located among vegetable and

fruit gardens our bees prefer this plant to all others.

It is not troublesome in cultivated grounds, but prefers the roadside or waste places. We value it highly, and without doubt, is worthy the attention of bee keepers. of bee-keepers. Denver, Col.

For the American Bee Journal.

# My Report for 1880.

W. D. WRIGHT.

I have to report the poorest season

I commenced the season with 165 colonies, some of them were very small. I received an increased of 63 swarms I received an increased of 63 swarms (mostly natural) and 4,503 lbs. of surplus honey, all from buckwheat (3,325 lbs. of the above was comb honey, the balance extracted). This gives about 38 per cent, increase, and an average of a little over 27 lbs. of surplus honey to each colony, against an increase of 65 per cent, and an average of 91 lbs. and a fraction (1 of which was comb honey). a fraction (\$\tilde{\xi}\$ of which was comb honey) of surplus honey to each colony last

season.
White and melilot clover yielded no white and include to the yelded ho honey this season, in this section. Bass-wood yielded well for three or four days and then stopped short, but as the hives contained but little honey at this time, the bees appropriated it for their own use, and they needed it much, as five or six weeks of scarcity followed this short flow. On August 10th, the bees commenced storring buckwheat honey, and continued moderately for about four

weeks.

I notice that several correspondents complain of the frequent failure of buckwheat to secrete honey. In this section it is our main dependence for surplus, and has not failed to give us a fair yield for the past six years.

My bees are all in one location, and there is probably 150 colonies besides, within a realize of one mile. I am constitutions

within a radius of one mile. I am confident that this locality was over-stocked this season, and think that I could have made as good a report from half the number of colonies.

Knowersville, N. Y.

For the American Bee Journal,

# Adulteration of Honey with Glucose.

L. H. SCUDDER.

Feeling as I do the importance of waging an incessant warfare against the use of the "vile stuff" in adulterating honey, sugar and syrups of all kinds, I desire to urge upon all the necessity I desire to urge upon all the necessity of agitating the question until we secure the passage of a law by Congress against the adulteration of food of any kind. It will be useless to undertake to secure the passage of a law simply to prevent the adulteration of honey, for way will not be able to secure the passage. prevent the adulteration of honey, for we will not be able to secure the neces-sary pressure to accomplish it. I re-cently had a conversation with our member of Congress on the subject, and he informed me that a general law pro-hibiting the adulteration of all articles of food would be more easily obtained, because more would be interested in the pressure of such a law if we could

passage of such a law, if we could cause them to see the importance of it.

We as homey producers feel the effects of the adulteration of honey keenly, because it is a death-blow to our business cause it is a death-how to our business unless we can secure protection. Just let me call your attention to a few facts in relation to the matter. First, please notice the fact that now with less than notice the fact that now with less than one-fourth of a crop of honey, there is no appreciable advance in the price of extracted honey? Why? Because "Glucose" is cheap and unprincipled men numerous, and so long as enough honey can be obtained to flavor the compound, the market will be supplied with "more honey." Notice the market quotations on extracted honey for the last three years and you will discover no fluctuation worthy of notice, notwith-standing the great difference in the annual products. Our friends have long been wishing for firm prices for honey, and they seem at last to have their wish 7 to 8 cents seems to be the fixed price at wholesale in Chicago for extracted honev.

Let me caution you not to be too con-Let me cannon you not to be too confident that even such prices can be obtained in the near future. Just note, if you please, how rapidly the manufacture of glucose is increasing; factories are being started in all parts of our country, enough are already in operation to consume five millions of bushels of corn annually in the west alone. Now of corn annually in the westalone. Now when you take into consideration the fact that they obtain over three gallons per bushel of what they call "glucose" or "corn syrup" you will see that over three gallons our markets to be sold and used in various ways. But mark you, not one gallon is sold to the consumer by its

know not of.

know not of.

If your druggist sells you poison the law compelshim to label it, that no harm may come of it. Then why not compel these men to do the same? Tis true they may not sell a mixture so destructive as arsenic or any of the deadly poisons, but just as certainly injurious as any of them. Now my friends, in justice to ourselves and humanity, let us continue our warfare until the people by their Representatives in Congress us continue our warfare until the peo-ple by their Representatives in Congress assembled, say to those men that their goods must be properly labeled and sold on their own merits.

I fancy when that is done there will be a decline in the Sulphuric Acid and old ray market. New Boston, Ill.

For the American Bee Journal.

# The Duplication of Queens.

D. A. PIKE,

It is not my intention to stir up the much-vexed question of queens duplicating themselves, but I wish to show to the readers of the AMERICAN BEE JOURNAL that it was no fault of mine that the test did not come off. I sent the queen to Prof. A. J. Cook on the 14th of June, according to contract. I did not hear anything from him direct until Sept. 12, but I heard from the edi-tor of the JOURNAL that Prof. Cook had received the queen, and he was rearing the queens to make the test. Here is what he says about the queen and her daughters:

Lansing, Mich., Sept. 2, 1880,
DEAR SIR: The queen came all right,
and was safely introduced; I feel certain
that I acknowledged her receipt at the time.
She is very beautiful, and her young queens
and drones have been greatly admired by
many visitors; her young queens are all
beautiful. I am very busy, but will try to
send you a queen soon. A. J. Cook.

The readers of the BEE JOURNAL The readers of the BEE SOURNAL will judge for themselves in regard to the queens. For their benefit let me say that I have had the albino bees since 1873; in my judgment, they have proved to be a superior race of bees; they are better honey gatherers than the Italiaus, and are more gentle to handle. Success to the AMERICAN BEE JOURNAL. Smithsburg, Md.

[As Prof. Cook is quoted in the above. we requested him to report the result of the test for the BEE JOURNAL, and it is as follows :-ED.]

Mr. Pike's letter gives me the opportunity which I desire, to rise and explain. The facts as given by Mr. Pike are wholly correct, though he fails to add that I wrote him that the young queens were not exact copies of the one he sent. I wrote the result to him, as he sent. I wrote the result to him, as he sent. I wrote the result to min, as I thought he was the proper person to give it publicity, inasmuch as I understood that the sequel had no importance so far as he and Mr. Moon's contract was concerned, as I supposed that was given up.

given up.

I repeat here substantially what I wrote to Mr. Pike. The queen was a great beauty, so every one said, and I showed her to many. Her worker progeny were also well marked, very bright and beautiful. Her drones were also exceedingly fine, the most highly colored ones I have ever seen. The young queens were also very beautiful, but not one was there which was not easily distinguished from the mother, and that. tinguished from the mother, and that, too, after they had fully developed and were well to laying. The workers were not all just alike, nor were the drones. These conclusions were not mine alone. but were those of my students and many others whose opinions I asked. I may add, that the colony did not equal some of my others in rapidity of increase, though it was a good one.

I believe this queen and her progeny

proper name, the dear people buy it in any other of our animals will perfectly their honey, candy, sugar, golden syrup, copy the parents, or be just alike. It is drips, and in other commodities we contrary to nature; and so Mr. Moon is

surely correct.

The nearest approach to perfect re-The nearest approach to perfect reproduction and uniformity of offspring, which I have met, is shown by the Palestine bees—Holy Land bees. This, of course, is the result of close in-and-in breeding by nature. While from the most severe selection of the fittest by most severe selection of the fittest by the same relentless hand, no deterioration, but rather the increase in excellence, have been the unvarying result. Yet even here we shall see variation from perfect uniformity. A. J. Cook. Lansing, Mich., Dec. 13, 1880.

For the American Bee Journal.

# Loss of Bees in Winter.

HIRAM ROOP.

We have often hinted in the BEE JOURNAL that one-half of all the bees were lost, each winter, in the Northern States. Our assertion was based upon facts, gleaned from a wide country, each spring, as to the condition of bees, how wintered, etc.

We are now having another severe winter what the result will be on the honey gatherers, is easily conjectured. We apprehend that two-thirds of the colonies in Michigan will be lost. Shall we, then, after a few ineffectual trials at a more rational method for safe wintering, sit down and allow this sweeping destruction to go on? We can winter, safely enough, in a good cellar. whiter, sales thought, in a glood centre, but, alas, the spring: for our part, we would rather have 100 colonies left out of 200 wintered on summer stands, than to have 150 left out of the same number wintered in any cellar or depository. Carson City, Mich.

# For the American Bee Journal Prevention of Swarming.

GREINER BROS.

When we take the above heading for our subject, it is not with the intention to take the position of instructors; we only wish to give our 5 years experience on this point, to show that it requires time and experience to get acquainted

with the business, and persistent labor to make it profitable.

Amongst other difficulties, swarming seems to take the lead in causing disappointments, and to illustrate this we will relate an incident, which came under our observation this season.

We had occasion to pass a neighbor, who kept some bees in the old fashioned box-hive way of letting bees have their own way, very frequently this summer, and the bee question formed a good share of our conversation whenever we met. These few colonies of our friend were nicely to work in boxes; they were filled with comb and honey ready to begin capping about the middle of June. The next time we passed, our neighbor met us with joyful countenance and informed us that his bees had swarmed, considering himself the lucky gainer of so many swarms. On questioning: "Do they work yet in boxes?" he answered; "No; they not only stopped working, but they have taken all the honey they had in the boxes, with them, when they swarmed." We learned at the close of the season, that our friend had only comb without honey for his share, his bees never went to work in said boxes.

Cases of this kind all bee-keepers have filled with comb and honey ready to be-

Cases of this kind all bee-keepers have experienced and it is a settled matter, that swarming must be controlled, the only question is, which is the most profitable way. To ascertain this, we have studied everything that has been written on the subject for the last 3 or 4 years, and have experimented on nearly all the different methods, which older beekeepers have pronounced the best. We would say here that we never had the

The different ways we have tried to prevent swarming are, distroying queen prevent swarming are, distroying queen cells, introducing empty comb in broodnest weekly. exchanging strong with weak colonies, dividing colonies, increasing by the shaking off process (see G. M. Doolittle, American Bee Journal, page 355, 1879), introducing a young queen, giving plenty of empty comb and chaff hive as non-swarmer. In the beginning of our bee-keeping errors a bee-keeping ferrors a bee-keeping ferrors as the seeping friend told us that

areer a bee-keeping friend told us that swarming could be very easily controlled by destroying queen-cells; we did not know any different at that time and consequently believed it. That season turned out to be a good honey year and as we had only transferred colonies (which are not very liable to

colonies (which are not very hable to swarm anyhow), under our eare, they did not swarm, to speak of.

The second year proved to be a good honey season also; a good share of our bees being transferred colonies, plenty of surplus room was given and all queen-culls dostroyed, they worked nicely in cells destroyed, they worked nicely in boxes and swarmed very little that year. By that time we believed in destroying queen-cells as an infallible means to prevent swarming and made our plans for the following senson accordingly and what was the result? The season failed what was the result? The season rather to give us any great amount of surplus. Honey came in just fast enough to keep bees breeding nicely, but too limited to induce them to work in boxes. Swarming time arrived and in spite of our districtions given only. distroying queen-cells, swarms poured out by the wholesale, our increased labors in cutting out cells availed us nothing; the more we worked the more these swarmed, with or without queencells.
We transferred, that season, 15 colo-

We transferred, that season, 15 colonies for a bee-keeping friend, he as well as ourselves felt very anxious, that these be kept from swarming and to accomplish this, we made it a point to examine them once a week, taking puriticular pains that no cells were overlooked. Everything went well until the latter of the second o licular pains that no cells were over-looked. Everything went well until the latter part of June; the next day, after we had again destroyed all queen-cells, a swarm came out, the next day another, the third day still another and the fourth day three more, and by the time we called again, a week latter, 8 of the 15 colonies had swarmed and before the season had passed, we had changed our ideas in regard to prevention of swarms destroying queen-cells.

We read, that the introduction of an empty comb in the middle of the broodempty comb in the middle of the brood-nest would keep a colony a week from swarming and also that bees with a young queen would not swarm. This we tried the next year; we had lost quite a number of colonies that winter and consequently had a good many combs at our disposition, these we used as stated, forming a new colony with a young laying queen of every 8 frames as sated, forming a new cooling with a young laying queen of every 8 frames of brood, which we took, one from a hive, to make room for the empty comb. Now did this keep our bees from swarm-

Now did this keep our bees from swarming? No; no more than did the distruction of queen-cells the year previous.

After that we divided our bees; this, if queen-cells are destroyed, will undoubtedly keep them from swarming, but on account of the heavy increase, eolonies are weakened too much for working in the boxes, consequently the object to produce the most surplus is missed. A better way is to increase by the shaking off process; we commenced with those that were making strongest preparation for swarming and by close watching and repeating this operation as often as other colonies would show any inclination to swarm, we kept the upper hand of our bees pretty well; but still they swarmed more than we wished and hoped for. We transferred 6 colonies late this spring, in June, and as honey was coming in plentiful at that time applied our section cases right off. time applied our section cases right off. One week after we divided or rather increased these by the shaking off process, giving the three sets of comb and a young laying queen. A week later, one of these three swarmed, this of course did not meet our approval for we wished to have them continue work in the sections as they had commenced, and for that reason we hived them back. and for that reason we hived them back, catching the queen and clipping her wings at the time, thinking that this operation would put a final stop to the ill-behavior of this unmanagable queen.

But no, another week and out they came But no, another week and out they came again, this time a queenless colony, for the queen was wingless and unable to fly; we picked her out of the grass and as soon as the swarm returned, put her back in the hive; this was their last attempt and the colony made us about 90 bbs. of comb bone this summer; the 90 lbs. of comb honey this summer; the whole lot has averaged 76 lbs. per colony from the original six.

We have also exchanged weak with strong colonies; this may have a ten-dency to keep both from swarming but

dency to keep both from swarming but it is by no means a certainty, and as we do not aim to have weak colonies in swarming time for that purpose, the plan cannot be very well followed up.

It has been supposed and remarks have been made to that effect, that a hive with sufficient chaff protection and plenty of empty comb would form a most perfect non-swarmer. To test this, we built a hive with about 4 inches of chaff all around, supplied the necesof chaff all around, supplied the necessary comb and transferred a colony into sary comb and transferred a colony into the same; we did not expect that this colony would do anything but work, at least not until all the combs were filled with brood and honey. But how great was our surprise, upon returning home from one of our weekly trips, to hear that our non-swarmer had followed suit

that our non-swarmer had followed suit by also giving a swarm.

To sum it all up, our 5 years' experi-ence has brought us to the conclusion that under our present circumstances, the shaking off process is the most desirable way of managing tokeep bees in working condition through swarming time, but if we could be with our bees time, but it we could be with our hees constantly, we would let them swarm the natural way. Of course, we would take the precaution to get our bees as strong as possible by the use of division boards and changing combs, and rear our queens in the forepart of the season to have them laying and read for use to have them laying and ready for use Then, when a swarm issues, we would hive it on the stand of the strongest colony that is the nearest ready to swarm and remove this one to a new location. The mother colony, which is then graphes a most heavening then are supported by the swarm and the strongest and the strongest are strongest as the stronges location. The mother colony, which is then queenless, must be provided with a young queen, and all queen-cells of those from which no swarms are desired, must be destroyed. The entire apiary should be managed in this way and by close attention and judicious application of surplus room an abundant crop of honey may be expected.

# Mating Queens in Confinement.

KING CRAMER.

For several years I have read in the AMERICAN BEE JOURNAL the different methods tried of mating queens in con-finement, and all the experiments that I have read of were made with a box or a barrel with a glass in the end of it. If a queen or a drone flies up and strikes that glass, there will be no more mating that day. There is no better way to kill bees than to let them butt against a glass. Not only that, who can tell just glass. Not only that, who can tell just the right time to take out the queen for confinement or mating? I at once saw that could not be practicable, and began some experiments, the result of which, together with the modus operandi of arriving at it, I purpose, with your consent, to lay before your readers.

I took a frame of brood, with as many young been as I could get, and not them.

young bees as I could get, and put them in the second story of a Langstroth hive, with a strong colony of bees in the lower story in order to get their heat for the occupants of the upper story, as the nights (about the 1st of September) were getting cold. Now we have a small swarm of bees in the upper story, with the honey-board between the bees below and those above, and also a honey-

board over the upper bees.
On the second day they were there I gave them a queen-cell. In two days it hatched out. I then gave them 10 or 15 young drones. Now I had the queen, young drones. Now I had the queen, drones and bees all confined in the upper story of the hive. The bees were fed and watered every morning.

The fertilizing box is 2 feet high, and its the hive on the top. It has a muslin cloth tacked over the upper end and the

t made a small hole 3 inches long and best, had queens bred from a colony  $\frac{1}{2}$  inch wide in the honey-hoard, and took the lid off the cloth, when the young bees and the drones flew around great foragers, being fully up to the within this box, as if they were flying reputation given them by Mr. Heddon. young oces and the drones flew around within this box, as if they were flying in and out of a hive. Every afternoon the lid was taken off the cloth 2 hours, and then replaced.

1 have 2 queens in my apiary that

and then replaced.

I have 2 queens in my apiary that mated by this process, and they were the only ones that I tried, as it was too late in the season to experiment further; but I can with safety say, that by the end of another season there will be hundreds of queens mated by this process, and fertilizing queens in confinement will be proclaimed a success. ment will be proclaimed a success.

# SELECTIONS FROM

Bees in Minnesota.—I am well pleased that the Journal is to come every week in place of once a month. Last spring I had I2 colonies, which were wintered in a dry cellar without losing any; sold I; increased to 22; obtained about 550 lbs. of comb honey, and plenty of honey for wintering. I bought 20 about 3.0 lbs. of combining, and prenty of honey for wintering. I bought 20 colonies of blacks in box hives last fall, for 560, making 42; then I heard of different persons who were going to kill their bees for the honey. I obtained permission to "drive" the bees out, and the matterious the property of the property o thus obtained 16 colonies more, all blacks. In December I bought all of Mr. Nelson Perkins' apiary, there being 30 colonies of Italians and hybrids, 30 empty hives, 250 combs in frames, extractor and boxes, making in all 88 colthey are wintering well to all appearance. It has been down to 40 below zero herethis winter. The farmers here are going to sow considerable Alsike clover in the spring. I intend to encourage it all I can, I will sow all the sweet clover I can in waste places. How sweet clover t can in waste places. Howeelose can I put my hives together in the spring and have them do well? Will it do to feed amber cane syrup to stimulate breeding in the spring?

WM. Lossing.

Hokah, Minn., Jan. 13, 1881.

I Four to six feet between hives at the sides, and 8 to 10 feet between, at front and rear, which will give ample room to manipulate one row without interfering with the next. We think a good article of amber cane syrup could be used to advantage for spring feeding. When the bees can pass in and out of the hives with perfect freedom, many kinds of feed may be sparingly given, which would prove disastrous if given in large quantities to winter on.—Ed.]

Bees had a Fly.—My bees are in fine condition, on summer stands, under a shed eight feet wide and fifty feet long. Yesterday was warm enough for them to take a fly, but to-day is very cold. I have not heard of any material loss of bees in this section this winter. I have received two copies of the Weekly Bee JOURNAL, and to say that I am pleased with it would not fully express my appreciation. I always expect to work for its interest and for the noble work in which it is engaged. I wish it a rich harvest this year. W. W. LYNCH. Maysville, Ky., Jan. 14, 1881.

Result of last Season.—With 56 colonies last spring (poor as the season was) I obtained a nice lot of honey. was) I obtained a life lot of honey. I purchased an extractor last spring and the result was really surprising. From 9 colonies I obtained 93 gallons or over 1,000 lbs. of as nice honey as ever graced 1,000 lbs. of as nice honey as ever graced a table or tickled the palate of an epicure. Of comb honey I cannot say to a certainty how much I obtained. I experimented with one colony to see what could be done scientifically and I obtained 79 lbs. of nice comb honey in small boxes. The others, to a great extent worked on the let-alone plan, gave me from 5 to 10 lbs. of honey or a fine cloth tacked over the upper end and the lid of the hive over that.

When the queen was three days old, of queens. Those colonies that did the

reputation given them by Mr. Heddon. I intend to give the Cypriansa thorough test next season. I expect to get two Cyprian queens next spring from Mr. Alley. I am highly pleased to have the BEE JOURNAL weekly, surely you have taken a step that bee-keepers may well feel proud of. I cannot understand how any one can undertake to keep hear without the allow the Perk Loure. bees without the aid of the Bee Jour-NAL. The writings of Mr. G. M. Doo-little in the American Bee Journal for 1880, were of infinitely more value than the year's subscription. In fact each number is a feast of good things to the apiarist. LEONIDAS CARSON Frederick, O., Jan. 7, 1881.

Sections.—Will you please advise me through the BEE JOURNAL, which size of sections would be preferable to adopt. of sections would be preferable to adopt. I am a new beginner in the bee business, and have not produced any comb honey as yet to speak of, and before making frames, buying sections, etc., I would like the opinion of some one experienced in the business, as to whether bees will store as well in the small 44x14 sections as in larger ones, and also whether honey in the larger sections will bring as good prices as in the small ones? Will bees store as rapidly where separators, are used as where they are separators are used as where they are not?

E. HUNT.

Sheridan, Mich.

[The market shows no preference between 1 and 2 lb. boxes, nor do the bees. we take negative grounds .-- ED.]

Too cold for anything.—The mercury froze up on January 8th and again last night at 10 p.m., and remained frozen until 6 a.m. to-day. The cold is intense. All business is suspended. The mercury has not been above zero since Christmas; much suffering prevails. I fear it will kill most of the bees here; many are dead now. Mine are still dry and nice being strong and well packed. The weather since Nov. I, ISSO, is the severest known to the oldest inhabitant. E. A. Morgan. E. A. Morgan. Arcadia, Wis., Jan. 14, 1881.

Bees in good Condition. -I had a light Bees in good Condition.—I had a light yield of honey the past season, but I doubled up my colonies and they have plenty of honey to winter on. They are on the summer stands and are at this writing in excellent condition. They have not had a flight since the middle of November. The weather has been steady and very cold. I hope you will make a success of the Weekly BEE LOUIS ALL for I think that it cannot be JOURNAL for I think that it cannot be published and read too often by the apiarist. Upon the close reading of the good experience of the many, our suc-

Pess greatly depends.
Davis, Mich. WM. P. EVERTT.

Dysentery.-I had 18 colonies last fall most of them well packed in chaff on their summer stands, and with plenty of sealed honey, but as soon as cold weather set in, they began to come out of their hives and die, till about one-fourth of them are dead, and the rest are in a very had combition. Same left fourth of them are dead, and the rest are in a very bad condition. Some left from 10 to 20 lbs, of nice capped honey in the hives. Some of the combs are badly daubed up. Will that honey do to feed other bees in the spring? Or will those daubed combs be injurious to young bees? I think it is dysentery caused by bad honey gathered late in the fall.

Trey Obio. the fall. Troy, Ohio.

[When the bees can fly in the spring, the honey, even though a little sour, will not injure the bees. The daubed combs will very soon be cleaned up by the bees.—ED.1

Cold.—It is 260 below zero here this morning, but we think it will not disturb our 136 colonies of bees very much. RUST BROTHERS.

Ellicottville, N. Y., Jan. 12, 1681.

Poor Winter for Bees.-The Weekly BEE JOURNAL comes to hand all right. I am well pleased with it contents, and I am well pleased with it contents, and only wish I knew how to get as much information in regard to bee-culture with the same money as I expect to receive from the Weekly in the next 12 months. The past season here was rather poor for bees, but I think they generally went into wither-quarters with enough honey to carry them through. The winter so far, has been very severe and bees that are neglected will be lost. I feel very easy about my well be lost. I feel very easy about my bees. I have them packed in chaff on their summer stands. I have wintered them in that way for the past 9 years.

JOHN I. MARTIN.

Falls City, Neb., Jan. 8, 1881.

Superiority of Italians.—Bees done poorly here last seaion. Many will die this winter for want of stores, though mine have plenty to winter on, except a few black colonies.—I took about 700 lbs, of comb honey from about nies: the Italians and hybrids leading the blacks about 75 per cent. Your valuable JOURNAL is read with much interest and profit. W. H. SMITH. Burlington, Iowa, Jan. 10, 1881.

Wants the Weekly.—You will have to change my subscription to the Weekly Journal. I subscribed for the Semi-Monthly but I cannot do without the Weekly Monthly have been good Northly Monthly but a cannot do without the Weekly. It has been a good Monthly and I have no fear but it will be just as good a Weekly. I wish you success.

Big Springs, Mich. J. Precious.

[We do so, with pleasure, and if there Opinion is divided regarding separators are any others who desire to change to being a hindrance, on which question the Weekly, we will with pleasure accomodate them.-ED.]

Cainip and Jessamine.—These are excellent honey plants in this locality—much better than others I see noticed in the BEE JOURNAL.

ALBERT E. FOSTER. Covington, Ky.

Wintering Well.—I am wintering 72 colonies, they are all right now, except one that is wasting away. I think more than one-half of the bees in this region are dead now. I must have the Weekly BEE JOURNAL. JAMES HARPER, Mason, Mich., Jan. 12, 1881.

Unprotected.—I hear that many bees are already dead where they are improtected. I am well pleased with the Weekly BEE JOURNAL. Now that we are to have its visits weekly, I think every one should renew their subscriptions promptly and send at least one powerful them. I will do all tens for new subscriber. I will do all I can for it in this region. M. A. Newman. Collins, Ill., Jan. 13, 1881.

Perishing by the Hundreds.—Bees are not wintering well here; they have been confined so long. They fly out, drop on the snow by the hundreds and perish. They have had no purifying flight since they have had no purifying flight since. Nov. 5. They worked on various kinds of decaying truit, and this is the chief cause of the difficulty. Send on the Weekly I cannot afford to lose a single copy.

D. W. Fletcher,
Lansingville, N. Y.

Uses the Langstroth Hive .- It has Uses the Langstroth Hive.—It has been rather a poor year for honey here in Maine. I had last fall 50 colonies, most of them in Langstroth hives, but some in Root's simplicity, and chaff hives. I put 23 colonies in cellar. I have had the best success there. I have used the Langstroth about 20 years, and I like it the best of any I have used, take it altogether, although I have had as good success in wintering in the America good success in wintering in the American. I have 27 colonies packed in chaff and straw on summer stands to try it.

LUCIAN FRENCH.

Dexter, Me., Jan. 13, 1881.

A Good Showing.—In 1879 I started with I Italian and I hybrid colonies.—Increased to 6, and wintered in cellar without loss. Next year they increased to 21, by natural swarming, and gave 500 lbs, of red clover comb honey, leaving plenty to winter on.
Taylor, Wis.

# THOMAS C. NEWMAN,

EDITOR AND PROPRIETOR.

CHICAGO, 1LL., JAN. 19, 1881.

EF Dr. N. P. Allen, President of the North American Bee-Keepers' Society, writes:

"The Weekly BEE JOURNAL cannot be surpassed in its mechanical appearance, as well as the valuable matter it

In Great Britain they have been exweather for many years past. It seems that the severity of the weather is general—at least in the Northern hemisphere. In the Autumn (says the London Mark Lane Express) storms, floods, frosts, and misettled weather over the whole United Kingdom seriously delayed wheat sowing.

Notwithstanding the fact that we commenced the year by issuing ten thousand copies of No. 1, the call for samples was so great, and new subscriptions so numerous, that in No. 2 we announced that we could not supply any more of the first number. Since that, we have found it absolutely essential to set the type again and have printed several thousand extra copies, in order to supply our new subscribers with that number to complete their files for the year. In addition to the almost unanimons renewal of the subscribers of last year, we have added over 500 new ones during the first half of this month. We knew there was a demand for a weekly bee paper, but had no idea that it was so general and persistent. The Weekly BEE JOURNAL is already established on a firm, paying basis, thanks to its friends and patrons. We fully believe in progression-no backward steps-and shall apply this to the Journal as well as to bees. To this end we now apply ourself with renewed vigor, and hope, by next year, to surprise our friends with still greater and more substantial improvements.

We have accepted an invitation to attend the Ashtabula County, O., Convention, which is to be held at Andover, O., on Tuesday and Wednesday, Feb. 8 and 9, 1881. On the evening of Tuesday, the 8th, we have engaged to deliver a public lecture on "Bees and Honey." There being a large number of beekeepers in that region, we expect the -as it has been changed.

pages and cover, on "The Introduction color, will solve the problem as to which and Early History of Bees and Honey." JOURNAL. Mr. Carr has our thanks for there would be less cause for so much the compliment of a copy.

last week's Journal...

# Selecting Location for an Apiary.

Last fall the burden of complaint, in many sections, was "scarcity of honey for bees to winter on," and now come reports from nearly every direction. saving "a great many bees will perish here this winter." Of course, the latter state of affairs is to a great extent the direct or indirect result of the former, occasioned by the early approach of winter, and its long continuation without the usual mild intermission. which rendered feeding impracticable with those who "trusted to luck" for an opportunity to feed before this time. contains. Every bee-keeper ought to In many cases dysentery has developed subscribe for it." -being packed away too warm, or not warm enough, or without sufficient periencing the coldest and most severe absorbents, and, in some cases, with improper food-their long continement rendering them peculiarly sensitive to defective preparation.

As a consequence, many bee-keepers will become dissatisfied with their present locations, and will turn their attention elsewhere for "fairer fields and pastures green," with a view to making bee-keeping more reliable, and to retrieve losses sustained during the past two discouraging seasons. such persons, and those about to embark in bee-keeping as a specialty, a few hints regarding the selection of a location for an apiary may not be out of place.

Be in no hurry about making your decision; or rather, start about it soon enough to allow yourself plenty of time to thoroughly canvass and investigate the different points under consideration. Locate where there is a profusion of white clover, with timber to the west and north, within range, where basswood or linden abounds; golden-rod, asters. Spanish needle and heartscase or smartweed abound in almost every locality, and where they do not, it is easy and profitable to put in a few acres of bnekwheat for late fall honey, as there is none better for wintering bees, and extracted buckwheat honey will always find a ready sale.

There are undoubtedly many locations in the country, yet unoccupied by the apiarist, where all the above requisites exist, and so far, nature has amply provided. A broken or low country is no particular disparagement, because the less desirable for cultivation, the more encouragement will there be for you to take time by the forelock, and plant plentifully of such honey plants as will insure a constant bloom, and provide against the time when others, encouraged by your success, shall go into beekeeping in your neighborhood and overstock the location unless nature is libermeeting will be very largely attended, ally assisted. With all the above natu-All interested will please notice the date ral advantages secured, aided by your provident forethought in planting, you will have done much to settle the ques-Mr. Wm. Carr, of Newton Heath, tion as to the best method of wintering, England, has issued a pamphlet of 16 and your bees, let them be of whatever is the best-race. We are often almost It is full of interesting matter. We persuaded, that were more attention will give copious extracts from it when devoted to selecting a suitable location we can find room in the Weekly BEE and to providing continuous pasturage, talk about procuring the best races of not necessary. bees; the bees reared 'neath Italia's

the superstitions and avoid the scorching suns of Cyprus, for their bees would gather no more honey than our own; turbed in the shade of its historic wall; and those in Caucasus would still fly from flower to flower in their own native valleys. What though we possessed a type of bees with the wings of a condor. with tongues as long as was that of Xantippe, and stomachs with a carrying capacity equal to that of Falstaff, of what avail are they if there is no honey to gather-no flowers yielding nectar?

In locating an apiary, avoid the close proximity of laurel thickets, as honey gathered from the laurel is unwholesome, if not really poisonous; avoid the neighborhood of eider mills, and do not locate immediately near a large body of water, as it will confine your bee-range to one direction exclusively. We would not like to advise the selection of a location already well stocked with bees, as it may be possible to over-stock almost any locality, unless some means are adopted to render it improbable. Many things are desirable in making a choice, and several positive disadvantages are to be avoided.

The Beautiful.-Of all malikind, beekeepers should admire the beautifuland we really think they do. Our bees, of the Italian, Cyprian and Albino varicties, are beautiful to look upon, and they sip the nectar from the loveliest flowers, hide it in dainty cells of matchbeauty and virgin whiteness. What is there, in all God's Creation, so soulinspiring as a cultivated garden of Nature's flowers, of variegated hues and heavenly grandeur? None but the unfortunate or despondent can fail to enjoy Nature in her garb of beauty. decked by the beautious hand of Deity. To produce a garden of living gorgeousness we may all aspire, and long enjoy its gratifying results.

These thoughts were awakened upon opening Vick's Floral Guide, which the morning mail brought to our desk. Of the many seed and Plant Catalognes produced by Seedsmen and Nurserymen, that are doing so much to inform the people and beautify and enrich our country, none are so beautiful, and instructive as Vick's Floral Guide. Its illustrations are are handsome, and given by the hundred, while its Colored Plate is a gem. This work, although costing but 10 cents, is handsonme enough for a Gift Book, or a place on the parlor table. Published by James Vick, Rochester, N. Y.

Questions.—1. How long can bees be confined to the hive, in cold weather, without any injurious effects?

- 2. When giving a matured queen-cell to a nucleus that has just started cells of their own, should the cells that are started be cut out?
- 3. When two or more swarms of black hees cluster together, is it best to hive them together, or divide them; and how could they be divided so as to get the queens?
- [1. If everything is favorable—feed, temperature, etc.—they will stand four months' confinement.
- 2. It is better to remove them, though
- 3. Unless very heavy, hive them to-The N. E. Wisconsin Convention skies would scarcely repay the expense gether. To find the queens, shake the was held yesterday at Oshkosh. We of importing; no longer would we tread cluster on a sheet, and while the bees are sorry the notice came too late for the shining sands of Syria in search of are scattered, the queens can be easily a better type; we could afford to respect distinguished and secured,—ED.]

# Our Climate Has Changed.

In Land and Water, C. M. C. makes the bees of China would be left undis- the following remarks upon the changes that have taken and are taking place in the American climate:

Since my early youth this climate has changed. The clearing away of the torests gives unimpeded sweep to northern winds; the leaves do not so long absorb and retain the fallen rains, and the treading of the surface by stock, all make the summer drier. There were make the summer drier. There were then one hundred springs where there is one now. The rills or creeks are gone or soon dry up, and scientific culture has to ward off the effects of drouth. If shallow plowing in the first breaking is made, the rush of the sarface water more than ever sweeps the soil. What remains is shallow, and the harsh winds and sun penetrate the roots, and the crop is injured.

Is it any wonder that our bees cannot gather as much honey as formerly, when the forests are swept away by advancing civilization, and the consequent cultivation of the land? This furnishes convincing proof that it now becomes a duty for bee-keepers to plant honeyproducers, in order to furnish bees with the nectar which they may gather. In this way only can we keep bees in the future with pleasure and profit.

# Hints to State Vice Presidents.

Daving the first three months of the year, the premium lists for County, State and District Fairs are usually made up. The Vice Presidents of the National Society should therefore soon commence their work.

We respectfully suggest that they communicate with the different official Boards of the Agricultural Societies in their respective States, and endeavor to induce them to offer appropriate prizes for BEES and HONEY at the Fairs for the coming season.

The following or something similiar to it would be well to recommend in the line of prizes:

Best package of honey in the comb, one pound or more.

Best package of extracted honey, one pound or more.

Best crate of honey in the comb, in the most marketable shape.

Best display of honey, both comb and

Best display of bee-keepers' supplies. Best colony of Italian bees.

Best exhibition with a colony of bees, in a movable-trame hive, including their public manipulation.

Best show of beeswax.

Best bee-hive for all purposes.

Those who have subscribed for the Monthly or Semi-monthly, and may want to change for the Weekly, can do so at any time by paying the difference.

# As Others See us.

Friend Newman, of the BEE JOUR-Friend Newman, of the BRE JOUR-NAL, published at Chicago, has made a new step in journalism, which marks also the rapid advance in the bee indus-try of this country. The BEE JOURNAL try of this country. The BEE JOURNAL which has for twenty years been published as a monthly, appears with its initial number for the new year as an s-page weekly. We welcome this evis-page weekly. We welcome this evidence of the healthy growth of the apiary and the enterprise of the veteran apiary and the enterprise of the veteran editor. The JOURNAL stands at the head of hee periodicals of this country, which includes that of the world, for America leads the world in the science and industry of apiculture. The JOURNAL is among our most welcome exchanges.—Kansas Farmer.

# BRITISH BEE JOURNAL.

The editor, Mr. Abbott, speaking of the late large importation of American honey in the comb, and that it produced quite a "scare" among English aniarists, says:

We must not, however, attempt to deny that the great import of American honey was a surprise, nor that it tright-ened many; nor will we pretend that its preparation did not exhibit a superior knowledge of the means of cultivating the bee to that which had been previously shown in this country, but we are glad to say that instead of producing general or permanent alarm, it acted as

Bee Education.—On this subject the editor remarks as follows:

The endeavor to establish a professorship under government has, unfortu-nately, not been quite successful; but great interest has been aroused, and there is reason to hope that in the en-suing year the application will be favor-ably received, when bee-culture becoming a branch of national education, the cobwebs of ignorance and superstition will be swept out of the apiary, and England will cease to be a laughing-stock among Continental bee-keepers.

Undiscovered Truths.—Comparing all that is known about bees with the yet unknown, Mr. Abbott says:

Turning now to the future, we cannot pretend to unveil what is hidden, we are told by Dr. Dzierzon, one of the greatest Continental bee-masters, that the little we know of bees is but as the sand on the shore in comparison with the treasures of the ocean; and we can scarcely hope that the waves of a year, or even a lifetime, will reveal them; but gradually they will be brought to light, step by step, one by one the second light; step by step, one by one, the se-erets of nature are unrayeled, and the mind of man bounds with delight as the beauty of the glorious fitness of things, and the mutuality of their relations are

Queen Excluders.—Upon this subject the editor remarks thus:

Zine with round-holed perforations was first brought into public notice for queen-excluding purposes by Mr. Obed Poole, of Uphill, Weston-super-Mare, in 1875; and a letter of his will be found on page 75 of the British Bee Journal for on page 75 of the British Bee Journal for that year, in which he stated that he had used it for some years. Mr. Poole also said, another good feature in the zinc is, I believe, that it is almost impossible for a bee to get through with a load of pollen; and this fact is an important one as distinguishing the roundholed zinc from the long-holed of later introduction. The zinc used by Mr. Poole had 3-16-inch perforations, but after considerable experience it was found to be a little too large; and on the recommendation of Mr. Cowan, that having 5-24 came generally into use; and it was with this kind we covered our new-idea frame of 1877, a full description of which was given in covered our new-idea frame of 1877, a full description of which was given in the Journal, page 62, of that year, and which Mr. D. A. Jones, of Ontario, is now introducing into America. Subsequent to that date, and through correspondence and personal contact with Colonel Pearson, of Nancy, France,—who will ever be remembered in comparion with improved the collustratives both. nexion with improved bee-culture both there and here—we were made aware that the late venerable Abbe Collin had been for years using sheet-iron with oblong holes in it for excluding purposes, and having obtained samples presently succeeded in obtaing the correct thing in zinc, as it is now largely used in all English apiaries. The round-hole perforation admits the body of a worker, but gives it a scraining success and research. but gives it a scraping squeeze all round thereby effectually prevention the pas-

sage of pollen. The Abbe Collin had as disastrons to bees as to the farmer in abandoned the round-hole on this very respect of his corn and hay crops, account, and adopted the long but nare. The result of the year's hee-keeping rower hole through which a bee queen cannot pass her thorax, while a worker can easily pass through with very slight pressure, and with no hindrance to her pollen-carrying.

# BEE-KEEPERS EXCHANGE.

First Importer,-Mr. C. J. Robinson says that "Mr. J. B. Parsons was not the first to import Italians into this country. Mr. Mahan, of Philadeldhia. Pal, was the first. He had charge of the Government and Mr. Parsons' bees while on their passage across the Atlantie. I mailed the first queen bee that went through the mails. It went to Rev. Langstroth who had the Parsons they are having a discussion on the adstock of bees."

Adulteration. - On this subject Mr. Nellis, the editor, has the following observations:

It is highly important that bee-keepers consolidate their efforts against the wholesale adulteration of sweets, which adulteration is very injurious to public health, and to the legitimate production of wholesale sweets.

The Exchange from its first numbers

until now, has put forth its efforts in the development of the honey market, and towards the suppression of the miserable adulterations that are now allowed to boast their ability to deceive the ignorant consuming public. The interests of producers and consumers can thus be promulgated in the same journal, and to this end the Exchange will bend its energies in the future.

We are glad to find Mr. Nellis on the right side of this question-but would prefer not to see the advertisement for glucose on the cover of the same paper. It is best not to touch or handle the filthy fraud.

# BEE-KEEPER.

As usual, this is filled with personal abuse; this time it is Prof. Cook who receives a good share of attention, but no disclaimer from him is necessary to persuade his acquaintances that he never used the language therein attributed to him. That the writer of the article was so informed we do not doubt, but more is required than the mere assertion (or even affidavit) of his informant, to convince any one that Prof. Cook made use of such an expression.

The paper is so badly printed as to be a disgrace to the art of printing, and with its persistently-repeated slanders and misrepresentations, it is a libel on the journalism of the world.

A writer in an exchange thus forcibly expresses his noble thoughts:

"A noble-minded person will never resent the omissions of others, or falsely construe their motives. The brave construe their motives. The brave only know how to forgive, and, as far as possible, to forget, real or imagined injuries; but the coward never forgives; he waits in ambush for an opportunity to strike in the dark or stab in the back. Small nimds are hurt by small events; but great minds see throughand despise them. True self-respect is always full of respect toward others, and wastes no thought on petty grievances.

# LONDON JOURNAL OF HORT.

The Honey Harvest.-The accounts which are coming in from various parts of the country giving reports of the honey harvest are various. In some counties hardly any honey seems to have been taken. The midland counties seem to have suffered worst in every way, owing to the deluges of rain following upon the constantly recurring honey for sa thunderstorms of June and July.— wrap the cl Of course this weather must have been paper pails.

The result of the year's bec-keeping above given, surely teaches the lesson Nil desperandion, and should encourage all to take the utmost pains and to spare no expense in feeding up their stocks of bees in good time during the warm days and nights of mid-autumn. Instead of all dying during the winter as they certainly would have done, and left me in beggary as an apiarist, my colonies of bees now number 12 all in good health and full of promise, worth at least 30s, apiece, in all £1s, and the profit of the year £13 additional, so that I am fully £31 better of than I should have been if I had despaired or neglected my bees as did so many of my hapless neighbors.

Straw Hive Controversy. - In England vantages of bar-frame hives, as compared with the old straw skep. Mr. Pettigrew is the champion of the latter and has thrown out a challenge to the bar-frame hive men to show results. Several of the latter are after him with facts and figures. Mr. Wm. Mann, who has been converted from the straw skep method, remarks as follows:

I do not keep a record of every hive. I do not keep a record of every live, but I did of one this year. It gave me 122 lbs, of comb honey in I-lb, sections, 30 lbs, extracted honey, and has over 40 lbs, left to winter on; yet I consider this has been a poor honey season. I sold the honey taken from this hive for £9 lls., and have my colony left to me well smoothed.

Mr. James Anderson, of Scotland,

Your correspondent has a good right praise his own system, but with your to praise his own system, but permission I will give one instance that permission I will give one instance that came under my own observation of the benefits of the Stewarton system in Arran this most productive season. From one colony James Crawford, a mason, obtained the following results: Old colony, 140 lbs.; first swarm, 187 lbs.; second swarm, 151 lbs.; total 481 lbs.

It seems very strange to us that in this age of enlightenment, any one (and specially Mr. Pettigrew), could be found to champion that old-fogy system of past ages. It is true, with good management and careful study, good results can be obtained from almost any hive in existence; and in this Mr. P. seems to rely for his supposed superiority of the straw hive. He is a careful and enthusiastic bee-keeper, and would have good results with any hive.

# BEE-KEEPERS' INSTRUCTOR.

We are glad to see the improved appearance of the Instructor. It makes a very creditable appearance typographically, and is full of good matter.

Selling Extracted Honey. - J. H. Marin thus describes his new plan for selling small quantities of extracted honey :

Provide yourself with a tray, or several of them; you can make them of wood, but they are better made of tin. Make the tray three inches deep, and two by three feet. Warm up your candied honey, so you can mash it into a homogeneous mass, and fill your tray. Now have several thin strips of wood, or tin three inches wide, and insert in or tin, three inches wide, and insert in the honey so as to cut the honey into cubes of 2\(^2\)\(^2\), and set your tray away in a cool place. It will soon candy solid, and you can then separate your cubes and you will have just a pound in such adds. In like prepare you can be a like prepare you can be a like prepare you can be a like prepared by the cool of the like prepared by the cool of the like prepared by the cool of the like prepared you can be a like prepared by the cool of the like prepared by the like prepared by the cool of the like prepared by the like each cube. In like manner you can make cubes of honey weighing three and five pounds.

Now place a neatly made glass case

in your nearest store and expose this honey for sale. Provide clean paper to wrap the chunks in or provide small

Shipping Queens. Mrs. L. Harrison gives her experience as follows:

Last season desiring to ship some queens by mail, we procured "Harris' provisioned mail and introducing eage," We forwarded a queen in one of these cages to Kansas, and in due time re-ceived notice that the queen and her attendants were dead, on arrival. We immediately mailed another one, in the Harris cage. Before doing so, however, we poured water into the cage until the provision was somewhat moistened, and provision was somewhat moistened, and also put in a sponge saturated with honey. This time the queen made the journey in safety. These cages are well made, and we consider the intro-ducing part alone, worth all that we paid for them. We would like to have others "tell their experience" with rovisioned mailing cages without any honey or water.

# Cook's Manual of the Apiary.

Nature, the most noted scientific journal in the world, is published in London, England. It has a long notice of the above named work, from which reprint the following extracts:

Prof. Cook's work differs from English works on the subject, in its combination of science with utilitarianism, while the amateur, pure and simple, is hardly recognized at all.

" More than one-third of the book is devoted to an account of the natural history of the bee, its place in the animal kingdom, its anatomy, physiology, habits and economy. Then follows the habits and economy. Then follows the chapters on bee-keeping proper; and the author here addresses himself almost exclusively to those who make bee keeping a business, and we are led to understand how much this branch of industry is advancing in America, where honey is now produced on almost as large a scale as corn.

"Prof. Cook has a chapter on 'marketing honey, 'tempting the consumer' and other mercantile details, and throughout the book we find constant indications that bee-keeping is looked upon as a business rather than a hobby and that, in all its details, economy of labor, and materials must be studied, and all processes judged by the test of the maximum of cost.

"An interesting chapter is devoted to honey plants," the principal species from which the bees obtain their honey in America being 'figured.'

"The English bee-keeper will no doubt obtain many useful hints from this excellent Manual of Bre-Culture, as practiced by our ingenious and energetic consins across the Atlantic.

霉 An old subscriber asks: "If I subscribe for the Monthly, shall I get all the matter contained in the Weekly, in a condensed form?" No; subscribers for the Monthly will receive the first weekly number (like this) published on the first Wednesday of each month, and will miss the next three numbers. Semi-monthly subscribers will receive the first and third weekly of each month (missing the second and fourth). Subscribers for the Weekly only will get all the reading matter. We advise all to take the Weekly who are keeping bees; it will pay them to do so. Any one who has subscribed for the Monthly or Semimonthly, can change to the Weekly upon paying the difference.

168 Please examine the date after your name on the wrapper label of this JOURNAL and see that proper credit is given. Such is often a sufficient receipt, now that the JOURNAL comes weekly. In the great rush of the past week or two, some mistake may have occurred which we shall be most happy to correct if our attention is called to it.

Read before the Michigan State Convention.

# Honey and its Adulteration.

J. P. H. BROWN,

I shall not task your patience by any discussion of the mere physical characteristics of honey. You are all familiar teristics of honey. You are all familiar with its history; but with its chemical composition there may be less famili-

Honey as secreted by the flowers, and when in its liquid state, has the same chemical formula of elements as frucor fruit-sugar, an uncrystilizable saccharme substance abounding grapes, figs and other fruit. It contains some coloring matter, a trace formic acid, gum, and a little mannite or manna-sugar.

After honey passes into the candied

After honey passes into the candled form and assimilates some of the elements of water, its chemical formula becomes similar to glucose which is also a saccharine product of fruits. The formula of glucose as given by Brand and Taylor, very eminent chemical authority, is C<sup>E</sup> II<sup>H</sup> O<sup>H</sup>, which may be read 12 atoms of Carbon and 14 atoms each of Hydrogen and Oxygen. each of Hydrogen and Oxygen.

From the fact that there is a similar-ity in the formulæ of honey and glucose, it is urged by the advocates of honey adulteration that glucose has substantiand the same physical properties as honey, and the same degree of whole-someness as food for the human organism. This is incorrect reasoning. ganism. This is incorrect reasoning. The premises are false. In organic chemistry there are many

substances that possess the same num-ber of atoms of the same elements, and yet their properties are most dissimilar. For instance, the oils of turpentine. lemon, bergamot, cloves and thyme are represented by the same formula, and yet their physical and chemical proper-ties are entirely different. On this sub-ject Brand and Taylor, the authorities previously referred too, observe: "When two compounds can be proved to be formed of the same elements in the same proportions by weight, it would appear to be a reasonable inference that their properties should be identical, but chemistry teaches us that this condition may exist and yet the substances be wholly different in chemical and physical properties. The fact is, the properties of the substance de-pend not only on the nature of the ele-ments, and the number of atoms of each, but on the mode in which these elements are grouped or arranged. Gum, starch and sugar are isomeric, or are constituted of a like number atoms of the same elements, and difference in their properties can there-fore only be ascribed to a difference of arrangement among these atoms.

Glucose, instead of being a natural product like honey, distilled in God's own laboratory in the flower, is a vile chemical preparation possessing proper-ties entirely different from honey, and ruinous to the health of its consumers. It is usually produced in this by boiling starch in dilute acids. Sul-phuric acid plays the most conspicuous part, but muriatic and nitric acids enter part, but marratic and nutric acids either also in its manufacture. A bushel of corn weighing 56 pounds will produce some 30 pounds of glucose, and the profits on a bushel is from 30 to 40 cents. Some glucose factories consume over 6,000 bushels of corn every day. This at a profit of 35 cents per bushel would amount in the neighborhood of a million dollars profit per annum.

It is now used in enormous quantities

ft is now used in enormous quantities for the purpose of adulteration and fraud in sugars, syrups and honey. Fally one-fourth of all the common grades of sugar consists of glucose. This accounts for the fact that the sweetening properties of our present syrups are might inferior to those used. sugars are much inferior to those used before the use of glucose. Two parts of cane sugar contain as much sweet as

wholly from glucose. Your "honey syrup," your "maple drip" and "rock candy drip" are all glucose frauds. A short time ago I saw a lot of nice glass jars in a large confectionary house in Augusta, Ga., containing a small plece of comb honey bathed in a clear syrup. On taking one up, I read: "Thurber's On taking one up, I read: "Thurber's Best Honey;" a little farther on, I read: "In order to prevent the honey from granulating it has been satuated with corn sgrup." Glucose! "Corn syrup"!! the d—, by a mild, euphonious name!!

There is no doubt but this nefarious practice of adulterating the food we eat, is daily on the increase. With this eat, is daily on the increase. With this adulteration, there is the notorious fact, that dyspepsia, derangement of the liver, and disease of the kidneys, are also increasing among the consumers of the trash that is sold for genuine. If the adulteration of honey is al-

the trash that is sold for genume.

If the adulteration of honey is allowed to go on without restriction, it will ultimately destroy the entire honey producing interests. It is somewhat of a problem, how can this trafic in fraud be restrained? Some advocate missionary work—warn the people against the use of fraudulent food, and point out to them the dire consequences attending its consumption. All this may be very well, and l do much good, ''Mora' and *earnest* prayer are power snasion susson—and carms prayer are power-ful; but there are cases where, I believe, it is necessary to use both prayer and carnest blows in order to make an impression. The love of sorting game non-dominant that men will adulterate— commit fraud, cheat and swindle— The love of sordid gain is so counterfeit the food we eat, and thereby deal out solid and liquid death to their fellows for dollars and cents. These cases are to be met by statutory laws rigorously enforced

am satisfied that petitions to the United States Congress will not avail. The work must be done by State legis-Adulteration is fraud. To sell idulterated food is cheating and swind-The penalty must be for fraud. cheating and swindling. New Jersey has some such law. Other states must has some such law. Other states must do likewise. When petitions fail it must be made a political issue, and must be fought at the ballot box. It is to be hoped that your Society will take the initiative, and set the ball in motion

in your State.

Read before the Michigan State Convention.

# About Poisonous Honey.

PROF. A. J. COOK.

To some of you it may seem unwise and impolitic to admit that honey is ever anything but nutritions and wholesome. But others, of whom our worthy brother Heddon is chief, think that the whole truth concerning our vocation should be told, even though the bitter is mingled with the sweet. But the facts to which I wish to call attention to-day are so exceptional that I think no one need fear the revelation.

The subject in question may, I think, be considered under two heads: 1st, honey poisonous because of the indihoney poisonous because of the mar-vidual peculiarity of the eater. In this case the honey has no markedly dele-terious qualities, for all honey affects these individuals alike; 2d, honey which has absortely poisonous quality, so that whoever eats becomes a victim to the noxious elements contained in the

presume that everyone present has known some person who could never eat honey, without serious incon-venience. My own farther is such an one. Indeed, he is so susceptible that all honey, even in homeopathic quantities, induces severe colic, attended with terribly griping pains. That this effect was due to his individual peculiarities, and not to the special honey is evident. and not to the special honey, is evident from the fact that all honey affects him from the fact that an noney anects mm in the same way; and further, honey which would cause him severe distress could be eaten by any of the other members of our family with perfect

impunity.

That this poisoning should be due to some constitutional idiosyncrasy is not hard to believe, for analogous facts are Our present syrups, unless genuine unable to eat cooked tomatoes without plantation, are manufactured nearly discomfort. Says Chas. Dadant: "I

cannot drink milk without suffering from colie." The following from the AMERICAN BEE JOURNAL, vol. 2, p. 231, is to the point: "Everyone is 231, is to the point: "Everyone is aware that certain persons have peculiarities about themselves which render them very susceptible to morbid impressions from causes which, on others, have no effect whatever.

"Physicians tell us that certain persons are very susceptible to the action of all mercurial preparations, one or two grains of calomel producing severe salivation, while others can take 20 or 30 grains without being in the least salivated. Some persons cannot eat cucumhers, nor sit at the table where they are served. Certain persons are afflicted with nettle rash (Urticaria) whenever they eat pork. Some persons are seized with a fit of asthma the moment a particle of the root called ipecacuanha is brought in contact with their hodles." At our Michigan Agricultural College our students have been called to work in a gewann whigh called to work in a swamp which abounds in poison sumach (*Rhus v.nc-nata*). Many can handle this terrible shrub without the least inconvenience, while others can hardly come in sight of it without becoming victims to the most intolerable pain and suffering, which sometimes persists for years. which sometimes persists for years. We conclude, then, that such cases of honey poisoning as are now under disenssion are due wholly to the individual. and not to the honey.

Mr. Langstroth (see American Bee JOURNAL, vol. 6, p. 221) and Mr. J. M. Marvin, in the same JOURNAL vol. 2, p. 188) claim that the cause of such colie is bee-sting poison, which is ejected from the sting of the bees, and lodged in the honey. It seems to me that this from the sting of the bees, and lodged in the honey. It seems to me that this view is untenable: 1, all honey con-tains the liquid secreted by the poison glands; 2, it is generally true that ani-mal venon, like that of poisonous snakes, is harmless if taken into the alimentary canal. It is not probable that bee venom is an exception. The more probable explanation is this: that all, or nearly all flower nectar contains some element that acts as a poison when some element that acts as a poison when taken into the stomach of certain persons. Whatever this element may be, it seems to be expelled, or converted into some harmless compound, by heat and by granulation. My father can eat honey that has candied with no difficulty. while the same honey, eaten before crystallization, caused him great distress. Heating the honey seems to work the same effect. I do not know whether it is necessary to boil the honey or not. If so, the quality of the honey would be injured. Mr. Chas. Dadant suggests that any one can overcome this unwelcome peculiarity by commencing to eat a very small quantity and con-tinually increasing. In this way the tinually increasing. In this way the body becomes able to resist all eyil effects, and the person may soon safely eat all that he craves. When we see how foolish men become able to take such poisons as tobacco and whisky ad libitum, if not ad infinitum, we can easily believe that Mr. Dadant is right. I have heard it asserted that fresh milk, if drank immediately after the honey is eaten, is a sure preventive of all attendant ills.

Our second point, that some honev is absolutely poisonous, so that all who eat will suffer, is well established.

Xenophon, in his account of the retreat of the ten thousand, as recorded in the Anabasis, recounts the fact that the soldiers sucked some honey combs near Trebizonde, where there were a great number of bee hives, and in consequence were attacked with vomiting and purging. So many were overcome that the ground was so strewed with their bodies as to resemble a field after a great battle. He states that none were lost, but that those who ate were unconscious for 24 hours, and did not regain their strength for three or four days. Tournifort, when traveling in Asia, investigated this matter, and cluded that the honey was gathered from the Rhododendron Ponticum, or the Azalea Pontica. Father Lamberti states that these shrubs are common about Colehis and that the honey at that those described by Xenophon. Dr. Darwin says that the honey from some plants is poisonous to man. Dr. Bar-all the more desirable.

on, of Philadelphia, in a paper published in the American Philosphical Transactions, says that in 1790 the honey collected near Philadelphia was fatal to many. Thorough inquiry, instituted by the government, determined that the source of this poisonous nectur was the Kalmia latifolia or mountain was the Kalmia lathona or incountain lannel. Bevan records the fact that two persons at New York died from the effect of eating honey gathered from the drawf laurel (Kalmia augustifolia).

Dr. Barfon states that Kalmia hirsuta,

Rhododendron maximum, or great laurel, Azalea mudiflora, Andromeda mariana, and the Datura Stramonium all produce honey that is poisonous both to dogs and to the human species. The symptoms, as given by Dr. Barton, are dimness of sight, vertigo, delirium, pain in the stomach and bowels, conpain in the stomach and vulsions, profuse perspiration, foaming at the mouth, vomiting, purging, and in some instances temporary paralysis, but very seldom death. Similar cases to those already narrated are detailed in the New Jersey Medical Reporter for November, 1852

J. Hammer, M. D., of Halifax Court House, Va., a physician in the confederate army, recounts, in Gleanings, vol. 3. p. 17, his own experience and that of several others, which agree almost entirely with what I have already given states that the honey was gathered from the mountain laurel, which grew in the Shenaudoah valley, Virginia.

About the middle of last October I received a letter from Mr. C., who lives in a neighboring state, in which it was stated that some honey sent by Mr. C. to some friends in New York city had produced serious sickness. All who are of it noticed that there was a who ate of it noticed that there was a sharp taste like that of cayenne pepper and that it produced coughing upon touching the throat. Suspicion being aroused as to its wholesome character, all but two present at the table refused to eat, though two children took one or two mouthfuls. The two who ate heartily, to quote: "Soon complained of nausea, vomited terribly, while their extremities became cold. They soon were unable to see. The children who tasted but little of the honey were troubled in the same way, but not so badly. A doctor was called at once, who gave an emetic and then whisky. who gave an emetic and then whisky. Soon all were well again. The pulse of the one who was troubled worst was for a time only 38 per minute. The doctor tasted of the houey, and was sick all night. night.

I sent to Mr. C. for some of the honey which he kindly sent to me. The comb honey is light colored, while some extracted honey which he sent, which is less poisonous, if at all so, is dark. Mr. C. says that all the honey which creates the smarting sensation in the mouth and induces the coughing, was certainly gathered before July 10th. These characteristics are so marked, that Mr. ', could, by simply tasting, select the honey that had the deleterious qualities. Mr. C. does not know from what plants

the honey was gathered.

I find that the honey received from Mr. C. has one other quality not mentioned above, it is bitter, so much so as to be decidedly unpleasant to my taste. I thought to try the effect of heat upon it, and so heated some of it till it boiled. I kept tasting of it during the time of heating, and also tasted of it after it head boiled. I could see no difference in the taste. Even after boiling for some minutes, it still was peppery and bitter. As my good wife objected decidedly to my eating it, I cannot, unfortunately, state whether the poison properties escaped with the heating or not, but the probabilites, I think, are that they did not.

cannot offer any very practical suggestions, I regret to say, on this subject. It would be interesting for Mr. C. to determine whether any of the species of Kalmia, Rhododendron, and Azalea, determine whether any of the species of Kalmia, Rhododendron, and Azalea, mentioned above, abound in his locality. Any good botanist of the region could inform him as to this point. The time of their blooming, as they all bloom in June. I think, together with the fact that they exist in a line south of him, in the states of New Jersey, Pennsylvania and Virginia, makes the inquiry all the more desirable.

Again, according to nearly all accounts—there is a little adverse testimony, it is true, but it is probably unreliable—this honey is entirely wholesome to the bees. If this be true, the honey may be fed to the bees in spring, and so not be lost. I should not fear to try this experiment of feeding it out, if I had any of this honey but from its

and so not be lost. I should not lear to try this experiment of feeding it out, if I had any of this honey, but from its bitter taste. I should deem it safer to try it in spring than in winter, though I presume it is a safe food at any season. From the fact that we only hear of this poisonous honey semi-occasionally, even in those regions where these noxious plants exist, is it not more than probable that these plants are not favorites with the bees, and so are not visited by the latter in quest of nectar, except in occassionally dry seasons, like the past summer in the eastern and middle states? It is quiet possible that these harmful plants have the power to resist drouth, like borage and catnip, and so furnish nectar, when the bees are unable to get it elsewhere, and we know bees will accept even glucose, if they can get nothing else. I have sufficient faith in this hypothesis so that I would encourage any present or future suffertaith in this hypothesis so that I would encourage any present or future sufferers to try again, in the hope that the long road which never turns was not the one traveled by their experience. I would also urge such person to ascertain whether the noxions plants named above are in their neighborhoods. Let all who live in the region where these laurels and their allies grow, carefully watch them, and note whether they are usually frequented by bees, and whether usually frequented by bees, and whether they do not secrete nectar in dry seasons when most other plants fail.

The Northeastern Bee-keepers' Association will hold their Eleventh Annual Convention, in the Common Council chamber, at Utica, N. Y., on the 2d, 3d and 4th days of February, 18st. The Executive Committee are determined to maintain the high standing the Association has justly gained in the past, and propose to out-do all former efforts at the coming Convention. Essays or addresses are expected from Capt. W. F. Williams; Prof. J. Hasbrouck; Mrs. Frances Dunham; James Heddon; Chas. Dadant; H. A. Burch; Jno. Y. Detwiter; C. P. Dadant; A. G. Thurber; W. A. House; A. J. King; Julius Hoffman and others.

A gold medal will be awarded for best essays, on

A gold medal will be awarded for best essays, on the following subjects: "The different races of bees and their crosses," "Wintering bees," "Marketing honey," "How can we make the apiary the most profitable?" profitable ?

For best essay upon any subject outside of those mentioned, one tested Cyprian queen, donated by L. C. Root.

C. Root.

Diplomas will be awarded for best display of implements; the best comb foundation for brood-chamber; for surplus boxes; best honey extractor; best bee smoker; for the most practical bee hive.

best bee smoker; for the most practical bee hive.
One dellar each, for the best crate of honey in the
most marketable shape, and for the best package of
extracted honey.

For the neutest and best boney crate and section
boxes (oset, quality and finish to be considered), one
del taken queen, donated by Gee, W. House,
All are invited to send implements for competition
or exhibition. Articles sent to the Secretary will be
sold or otherwise disposed of as the owner may
direct. It is desired that all articles sent be the same
as kept in stock, or forwarded to purchasers
GEO. W. HOUSE, Sec. L. C. ROOT, Pres.

The Nebraska Bee-Keepers' Association will hold their Annual Convention, on the 10th and 11th of February, 1881, at Plattsmouth, Cass Co., Neb. Western Iowa bee-keepers are cordially invited to attend.
HIRAM CRAIG, Pres.

The Rock River Valley Bee-Keepers' Association will hold their annual meeting at Monroe, Ogle county. Ill., on Feb. 8, 1881. The weather was such that our Secretary was not at our last meeting and our Secretary protem having failed to send in his report, 1 send the above notice.

A. Rice, Pres.

The annual meeting of the Sonthern Michigan Bee-Keepers' Association will be held in Battle Creek, Mich., on Wednesday, Feb. 9, 1881, at 10 o'clock a.m. B. Sallsbury, Sec.

The Champlain Valley, Vermont, The Champian valley, Vermont. Bee-Keepers' Association will hold its annual meeting in Brandon, Vt., on Thursday and Friday, Jan. 20 and 21, 1881. H. L. LEONARD, Asst. Sec.

Sample copies of the Weekly BEE JOURNAL will be sent free to any names that may be sent in. Any one intending to get up a club can have sample copies sent to the persons they desire to interview, by sending the names to this office.

# CLUBBING LIST.

We supply the Weekly American Rec-Journal and any of the following periodicals, for 1881, at the prices quoted in the last column of figures. The first column gives the regular price of both:

# Honey and Beeswax Market.

BUYERS' QUOTATIONS.

# CHICAGO.

HONEY.—Light comb honey held at 185/20c. in 1 nd 2 fb. sections; in larger packages, 159/16c.; dark, 5a/1c. Extracted, 9a/10c.
BEESWAX.—Choice yellow, 20/2/2c; darker, 15/2/17.

## NEW YORK

NEW YORK.

HONEY, Best white comb honey, small nent packages, 18629c.; fair do., 156 lie.; dark do., 16645; large boxes sell for about 2c, under above. White extracted, 9620c.; dark, 568c.; southern strained, 8068x.

BEESWAX.-Prime quality, 20m24c. H. K. & F. B. Thurber & Co.

# CINCINNATI.

HONEY.—The market for extracted clover honey is very good, and in demand at 10c, for the best, and 7csc. for basswood and dark honey. The supply of comb honey is good, with a fair demand. We pay like for the best. ic, for the best. BEESWAX-18@24c. C. F. MUTH.

# SAN FRANCISCO.

Your new Weekly is at hand; it is cleanly printed and full of interesting bee-reading matter. Our market is unchanged from last quotations and queet, as there are no buyers for European account at pres-

as there are no bayers for Dancys and ent.

# The Horse

BY B. J. KENDALL, M. D.

A TREATISE giving an index of diseases, and the symptoms; cause and treatment of each, a table giving all the principal drugs used for the horse, with the ordinary dose, effects and antidote when a poison; a table with an engraving of the horse's teeth addifferent nees, with rules for telling the age of the horse; a valuable collection of receipts, and much valuable information.

Price 25 cents,—Sent on receipt of price, by

THOMAS G. NEWMAN 974:West Madison Street, CHICAGO, ILL.

# Books for Bee-Keepers.

Cook's Manual of the Aplacy. Entirely rewritten, greatly enlarged and elegantly illustrated, and is fully up with the times on every conceivable subject that interests the aplarist. It is not only instructive, but intensely interesting and thoroughly practical. The book is a masterly production, and one that no bree-keeper, however limited his means, can atord to do without. Cloth, \$1,25; paper covers, \$1,00, postpaid. Per dozen, by express, cloth, \$12; paper, \$2.0.

Apriles, 'S. New Bree-Keeping, by L. C. Root The mither has treated the subject of bee-keeping in a manner that cannot full to interest all. Its style is plin and breitle, making all its renders sensible of the fact that the author is really the master of the subject. Price, 81, 550. Novice's A B Cof Bee-Culture, by A. I. Root

This embraces "everything pertaining to the care of the honey-bee," and is valuable to beginners and those more advanced. Cloth, \$1.25; paper, \$1.00.

King's Bee-Keepers' Text-Book, by A. J. King. This edition is revised and brought down to the present time. Cloth, \$1.00; paper, 75c.

Langstroth on the 111ve and 11oney Bee This is a standard scientific work. Price, \$2.00.

Blessed Bees, by John Allen.—A romance of ee-keeping full of practical information and con-agious enthusiasm. Cloth, \$1.00.

tagious entinesiasia. Cioli, \$1.00.

ReceCulture; or Successful Management of the Aplary, by Thomas G. Newman,—This pampillet entireres the following subjects: The Location of the Apary—Honey Plants. Queen Kenting—Feedin;—Swarming Dividing—Transfering-Indianizing latroducing Queens—Extracting—Quieting and Handling Boss—The Newest Method of Frequeing Honey for Market, etc. It is published in English and German. Price for either edition, 40 cents, postpaid, or \$3.00 per dozen.

Food Adulteration; What we cat and should not eat. This book should be in every family, where it ought to create a sentiment against the adulteration of food products and demand a law to protect consumers against the many health-destroying adulterations offered as food. 200 pages. Paper, 50c.

The Dzierzon Theory; -presents the funda-mental principles of bee-culture, and furnishes a condensed statement of the facts and argaments by which they are demonstrated. Price, 15 cents.

which they are demonstrated. Price, 15 cents.

Hnney, as Food and Medicine, by Thomas G.
Newman.—This is a pampillet of 24 pages, discoursing
upon the Ancient History of Bees and Honey; the
nature, quality, sources, and preparation of Honey
recipes for making Honey Cakes, Cookies, Paddings,
Foun, Wines, Ac; and Honey as Medicine, followed
by many useful Recipes. It is intended for consumers, and should be scattered by thousands all over
the country, and thus assist in creating a demand for
honey. Published in English and Germann. Price
for either edition, 6e.; per dozen, 50c.

Wintering Bees.—This pumphlet contains all the Prize Essays on this unportant subject that were read before the Centennial Bee-Keepers' Associa-tion. The Prize—425 in gold—was awarded to Prof. Cook's Essay, which is given in full. Price, 10c.

Hees and their Management. This pamphlet was assued by the Italian Bee Company, and has had a large circulation. The price has been reduced from 20 cents to 10 cents.

The Hive I Use-Being a description of the hive used by G. M. Doolittle. Price, 5c.

Kendall's Horse Book - No book can be more useful to borse owners. It has 35 engravings, illustrating positions of sick bases, and treats all diseases in a plain and comprehensive manner. It has a large namber of good recipes, a table of doses, and much other valuable horse information. Paper, 25c.

Chicken Cholera, by A. J. Hill.—A treatise on its ause, symptoms and care. Price, 25c.

Moore's Universal Assistant contains information on every conceivable subject, as well as receipts for almost everything that could be desired. We doubt if any one could be induced to do without it, after having spent a few hours in looking it through. It contains 480 pages, and 500 engravings. Cloth, 82, 50.

Ropp's Easy Calculator.—These are bandy tables for all kinds of merchanduse and interest. It is really a lightning calculator, nicely bound, with slate and posket for papers. In cloth, \$1.00 : Moreco, \$1.50. Cheup edition, without slate, 50c.

# Over-stocking and Planting for Honey.

C. II. DIBBERN.

The present season has been one of discouragement to many bee-keepers, in this section. It has required a good deal of "love for the business" to pay any attention to the bees at all, all through, what should be our honey harvest. All though I did a good deal of feeding, yet swarms would issue every few days for want of stores. Basswood gave us the first promise of comb honey, but as nearly every cell in the main hives were empty, they stored but little. After basswood there was great drouth, and the apiary was about as quiet as a graveyard. About the middle of Aug. the bees commenced on buckwheat and the fall blossoms, and did very well, but as their stores had become very light, it took about all they gathered to put them in fair condition for winter.

Mr. Dadant mentions hauling bees to The present season has been one of

Mr. Dadant mentions hauling bees to the Mississippi river bottoms that had been overflowed, with good results. Here these bottoms were nearly as bare

Here these bottoms were nearly as bare as the streets of a city.

Is there not a lesson in the past year's experience that every intelligent beckeeper should heed? I am glad to notice that "over-stocking" and "planting for honey" is attracting attention in the BEE JOURNAL. Over-stocking is a greater evil than most of our friends suppose. "A" has but 200 colonies and thinks his location "not over-stocked:" but there are from 100 to 200 more withthinks his location "not over-stocked!" but there are from 100 to 200 more within 1½ miles in all dieection. Would he not be better off, as far as his bees are concerned, if he had these 700 or 800 colonies all in his own yard? Then they would all have an equal show, which they have not now.

Most of as have seen tract after tract of our choicest "bee range" fenced and plowed up and devoted to potatoes and other crops of no value to the bees

other crops of no value to the bees
In many localities bees have increased from a few colonies to hundreds, while

the pasturage has greatly decreased. There is no other branch of business, that depends entirely on a volunteer crop. Now over-stocking will not remain "an imaginary evil" unless there is some kind of proportion between bees and the honey sources in any locality.

locality.

Why is it that so many think it does not pay to plant for honey? The trouble is that bee-keepers lack that confidence in their business so necessary to success. I have known patches to be sown "for the bees" 10x20 feet, and because honey did not flow into the boxes the long summer through, the arrange goverheads it did not true. owner concluded it did not pay.

For the American Bee Journal.

# Apiculture-What is it?

C. B. WOODMAN.

Upon this subject I shall write wholly from experience. I had, for a long time, contemplated the manipulation of bees and the production of honey, but to accomplish this desire was a "trick" or science I knew nothing about I determined, however, to make an attempt, I purchased two colonies of Italian bees in Langstroth hives, next procured specimen copies of all the been papers for inspection and my considerapapers for inspection and my considera-

minimi

The far-famed Honey-Producer—Basswood or Linden.

I have experimented a good deal with

I have experimented a good deal with honey plants during the last 15 years and think melilot clover is the king of all.

Now if bee-keepers would plant say one-quarter as many acres as they have colonies of bees I think they would be astonished at the result. But we are apt to think too much of the number of bushels of potatoes or corn that these acres would produce, to ever give it a fair trial. fair trial.

tair trial.

It is my opinion that the "bee-keeper of the future" will have unbounded confidence in his business, and will look as closely to the number of acres of honey-producing plants as to the kind of hives, bees and sections.

Milan, Ill., Dec. 5, 1880.

tion; I finally settled down on the reliable AMERICAN BEE JOURNAL and with the perusal of other prominent works on the subject, such as Root's "A B C," Langstroth's "Honey and Honey Bee" and Quinby's "New Bee-Keeping." I found the trick no trick at all. I am highly pleased with the pursuit, and would not despair under any provacation. I use the standard Langstroth hive and winter in the cellar, with such

cation. Tuse the standard Langstron-hive and winter in the cellar, with suc-cess. I think any one contemplating going into the business of apiculture would be pleased with it and will surely succeed it they have a love for the calling, and start as 1 did. I heartily recommend Quinby's "New Bee-Keeping" for the beginner, and under its

teachings failure would be almost impossible. A Monthly, or Weekly beepaper is another of the indispensables, pertaining to successful apiculture.

Johnson's Creek.

For the American Bee Journal,

# Alsike and Melilot Clovers.

J. II. MARTIN.

J. II. MARTIN.

I was much interested in the article by Mr. Baldridge in the JOURNAL for Jan. 5th, upon alsike clover for bee pasturage; I have experimented with it sowing a small field and found the bees worked upon it equal to his recommendation. But it blossomed only one year, the next there were but few heads. Others have had similar experience in its non-propagation of itself the third year. We would like further particulars from Mr. B. in relation to sowing the seed, should it be sown alone or with timothy, and should it be gathered with a header?

We wish also to learn the proper time for sowing melilot clover seed. We have some in our immediate locality, but there is plenty of it a few miles from us upon heavy clty soil. I gathered a quantity of seed from the roadside, and sowed it on all waste places along the highway in my own locality. Our soil is gravely loam but not a seed sprouted. I sowed in the fall immediately after gathering, thinking it would sprout in the spring the same as though it had fallen from the parent plant.

sprout in the spring the same as though it had fallen from the parent plant.

I have also had poor success with Simpson honey plant. Our soil is rich loam and a good farming country. How shall I get my seed to grow?

Hartford, N. Y.

[As requested, Mr. Baldridge will no doubt answer these questions.—ED.]

For the American Bee Journal.

# Wintering in the Cellar.

E. A. THOMAS.

A dry cellar is considered requisite for successful wintering by nearly all bee-keepers, but my experience teaches me that it is immaterial whether the cellar is dry or wet, provided, proper ventilation is given. I have always wintered successfully in a damp cellar and never lost a colory.

ventilation is given. I have always wintered successfully in a damp cellar and never lost a colony.

My cellar has a stone floor, which I think is a very good thing as it enables me to sweep up all the dead bees and keep the room pure and fresh.

My hives are placed on racks which stand on the floor, so that nothing short of an earthquake can jar them. There are four ventilators to the room, one to the open air, one through a drain, and two in a chimney at top and hottom. By means of these I c in keep the temperature very even. In extremely cold weather, and in warm spring weather I keep the open air ventilator closed, and ventilate through the drain, which warms the air in cold weather and cools it in spring.

I believe in order to winter successfully in cellar, we should give the bees plenty of fresh, warm air, not letting the temperature vary more than 32 or 4, and keep them perfectly quiet. Much also depends on their management during the fall months, for if they go into winter-quarters in poor condi-

go into winter-quarters in poor condi-

tion, they can hardly be expected to any such speculation should make.

tion, they can hardly be expected to come out in good condition. During the windy days of late fall, when the sun shines warm on the hives, causing many bees to venture out and perish, I shade my hives and so keep my bees at home. Much has been said about spring dwindling but very little about fall dwindling, which I think is just as necessary to prevent. I endeavor by every means in my power to keep my bees quiet in their hives during the rough, windy weather of late fall. perish, I shade my hives and so keep my bees at home. Much has been said

I put them in the cellar very early when the hives are dry and free from frost, and keep them perfectly quiet, with the thermometer standing at about

45, until late in spring.
Under the above conditions my bees come out very strong in spring, with clean, dry combs.

# My Experience in Starting an Apiary.

E. NUGENT, M. D., F. R. C. S. I.

Being determined to embark in bee-culture, I went to the Toronto Industrial Exhibition last fall, where the first Canadian Bee-Keepers' Convention was Canadian Bee-Keepers Convention was held, and proved successful beyond con-ception—thanks to the untiring exer-tions of D. A. Jones, of Beeton, Ont. Matters of great interest were discussed anatters of great interest were discussed at numerously attended meetings and the Ontario Bee-Keepers' Association, formed and liberally subscribed to. I had a good deal to learn and was fully satisfied at the prospects bee-keeping offer, as shown by those present who were fully competent to give an opinion.

I then engaged the services of Mr. Conklin, one of Mr. D. A. Jones' late assistants, who was highly recommended by that gentleman, and then I set about purchasing 200 colonies, which set about purchasing 200 colonies, which I fancied would not be a very hard matter, especially when I had made up my mind to give a good price for good stock; but in this I was doomed to disappointment. At first I had agreed for 200 to 250 colonies, my pick out of 325, that were represented as first-class colonies but in looking them over, with my man we could not get more than 50 nies" but in looking them over, with my man, we could not get more than 50 at the outside, and of these only about a dozen which my man and I would care to accept. Then I turned my mind to the States as a tield to purchase from, and had again arranged with a party for 250 colonies, my choice out of about 400 first-class colonies; but on visiting the locality, was again doomed to dis-appointment. The bees were not there to choose from, and then after visiting appointment. The bees were not there to choose from, and then after visiting other bee-keepers, friends of the gentleman, in the neighborhood could get tleman, in the heighborhood could get perhaps 100 which we much preferred leaving than taking, at a much reduced figure, or indeed at any figure, though the representations made to me in letters were quite assuring. You can fancy the disappointment to a man being brought over 300 miles on such

representation.

My man then tried Dowagiac, Mich. where contrary to my expectations and the unpretending letters of Mr. Hed-don, we found everything quite beyond all our ideas. About 450 colonies at the two apiaries, all the hives Langstroth and modified Langstroth's, neatly and well made and painted. Honey-boards, marvels of neatness and simplicity; frames, covers, and all in keeping with each other, and not slammed over in workmanship; the sections used perfect pictures and jars for honey that would make any one purchase the contents, were it but for the jaralone; in fact, all here was a complete contrast to the other heaps of confusion, starvation, vermin and dirt visited. No wonder some bee-keepers fail—failure is the proper thing for them, and the sooner bee-keeping becomes a better-cared for business, the better. I would strongly advise those who desire to travel to visit apiaries not to overhook those at Dowagiac and Glenwood, Mich., and if they are not pleased with their management, I shall gladly learn where to see better. pictures and jars for honey that would

I am commencing bee-culture and wish to make such fair interest for money invested, as one entering into tuseness on my part, but I could come

want to learn all 1 can and turn it to bad indeed reported me dead. But, on account, and should I succeed, I hope to submitting the extract to another, his establish more than one bee farm. No doubt it will admit of such development, and I think the day is not far distant when we shall see bee-keeping taken up by a far greater number of persons

My 200 colonies cost me much more My 200 colonies cost the infici more than they would, had I been able to get such stock as I required in Canada, where I could have saved 20 per cent. duty, and paid less freight than \$76,20, which it cost me from Dowagiac here. which it cost me from Dowagiac here, as also expenses going there in search of them, and this is no small item to a beginner, and unless bee-keepers realize this fact, that "what is worth doing at all, is worth doing well and right," they cannot expect to succeed any more than in other neglected pursuits. There is no use in a person starting without capital, but no matter how little he may bright the golden rule is to little he may have, the golden rule is to "keep within your means." for the idea of getting something out of nothing has been too often tried with just the same results.

same results.

I have built a bee-house, 22-in, clear walls, chaff packed, ventilated above and below, and I fancy for its size (20x 28 feet) the best in Canada. I have purchased 200 selected colonies of Italians, hybrids and a few blacks. I have a first-rate location, and should I not a mistrate location, and smouth I not do as well next year, as I expect, I shall not blame Mr. Heddon, nor shall I throw up the sponge in despair. I shall try on, and endeavor to find out causes of failure, improve or rectify as the case may be, and hope. Mr. Editor, to give you a correct account in due time of either success or the reverse.

Strathroy, Ontario.

For the American Bee Journal.

# Clarke Redivivus.

WM. F. CLARKE.

I think I may fairly claim to be the Rip Van Winkle of American apiculture. Shortly after my transference of the American Bee Journal to Mr Newman, I became so unsettled in my circumstances, as to render bee-keeping out of the question. One cannot write on apiculture and keep up with the times, without being actually engaged in the business, at least in a small way, so my pen came to a stand-still. Then, so my pen came to a stand-still. Then, three years of ill-health sepervened, necessitating retirement, quiet, and rest. About the time I had got recuited, and was meditating re-entrance on a and was medically rectanice of a more active life. I found to my surprise and chagrin, that, as in the case of the veritable and historical Rip Van Winkle, the impression was abroad among kle, the impression was abroad among my old friends that I was dead. A circular issued by Wm. S Hawley, of Rochester, came into my hands, in which the following passage occurs: "The Rev. Mr. Clark, late editor of the American Bee Journal, the man who later accidently got a bee in his mouth while drinking, and died from the effects of baying been stung on the

the effects of having been stung on the back part of his tongue, and in short, others who have lost their lives in one way or another in handling bees, will not be apt to ask to be placed in the 'Don't-care-if-they-do-get-stung' army of bee-men.

The above extract was sent me by A. I. Root, and it certainly read like an obituary notice. I therefore penned a brief communication to Gleanings informing the bee-keeping fraternity that I was still alive and kicking: "-Whereupon I received a letter from Mr. Haw-

ley in which he says: "I presume you have read the articles in Bee Journal, Gleanings, and the Magazine. The first accuses me of lying; the second of reporting you dead: and the last of an attempt to swindle bee-men out \$10 each; to all of which I plead not 'guilty.'....Now, I ask you as a friend to read the extract from my circular again, and construe it as your better judgement dictates. If from it I am to be convicted of charging your death, I must abide by the decision of the court.

I to no other conclusion than that Hawley submitting the extract to another, his critical acumen discovered a loop-hole which I had failed to detect. He thought the passage might be meant as an enumeration of cases in which beestings had proved dangerous or fatal, and that "the Rev. Mr. Clark" and "the man who later" died from the effects of a bee-sting in the tongue, were two distinct personalities. I give Mr. Hawley the benefit of the criticism, and exonerate him from the charge of Mr. Hawley the benefit of the criticism, and exonerate him from the charge of reporting me dead. But the construction of the sentence is such as at first sight to convey the impression which I and others received. The sentence is a queer one anyhow. It contains a genum Trich hull. The headerplets received. queer one anyhow. It contains a gen-ume Irish bull. The bee-keepers referred to who are dead and gone, will certainly not "ask to be placed in the "don't-care-if-they-do-get-stung" army of bee-men." or any other army since of bee-men." or any other army, since they belong to the silent host of the departed. For myself, I frankly own, that I belong to the timid class of beekeepers, who

# DREAD A BEE-STING.

I cannot, as many do, fondly call the bees "my pets," for they have always refused to be petted by me. I could never enter them on my list of friends. They have invariably acted the part of enemies toward me, and have persecuted me without cause. Nevertheless. I had become so habituated to their stings, that I did not care much for them. I used to handle my bees without vail or gloves, taking my chances. I always managed to protect my face by keeping it shaded with a broad-brimmed hat, inclined at a pretty acute angle. But, on one unlucky day, a waspish Italian got his dagger into the point of my upper lip, just where the monstache divides, and I have had a profound respect for a bee-sting ever since. I shall never forget that sharp experience, "while memory holds her seat." It is not surprising, therefore, that I have read with nterest Mr. Hawley's manifestoes about

# STINGLESS REES

with more interest than faith however, 1 am a natural born unbeliever upon many subjects, and must have the proof before I repose confidence. In com-mon with most bee keepers who have philosophised on the subject, I have been led to regard the sting as an important appendage to the honey-bee. I think the Creator had a wise design in arming this little insect with a formid-able dagger. As I have said in my prize poem,

# "The bee 's a warrior bold,"

and the warlike propensity in the bee is and the warfike propensity in the bee is like the same propensity in man. It is meant for the protection of precious interests and vested rights. The com-bative element in man is intimately connected with that quality of energy which is so essential to success in life. which is so essential to success in life, and I am inclined to think it is much the same with the bee. As a whole-some dread of the law keeps many theives honest, so a like fear of beetings the same of the same with the same and the same are same as the same are same are same as the same are same as the same are same are same as the same are same as the same are same are same are same as the same are same as the same are same are same are same are same as the same are same as the same are same ar stings prevent nocturnal marauders from robbing hives. Mr. Hawley's ac-count of the Brazilian or stingless bees

# HARD TO BELIEVE.

He has been able to find but one in-Brazil. That was in Germany. The experimenter claimed that these bees were far more prolific; that they stored were far more prolific; that they stored on an average fully a guarter more honey than the German-bees; that they had longer tongues; that they were more hardy; that they were more hardy; that they were not addicted to robbing; that the queens would not mate with other drones; that they are as large as the Italian, and quite as handsome. All these good qualities, and no stings! Truly this is the apis angelica! O for an apiary of them! They would be "pets" in spite of themselves! Wouldn't I caress and fondly them, even if they buzzed discontent at my loving attentions! But fondly them, even if they buzzed distance the casual observer sud-content at my loving attentions! But I cannot help thinking that if such a race of bees had found their way to Germany, there would be more than one instance on record of their being tried. Our transatlantic brethern would not have been blind to their same position it occupied in the hive,

angelic attributes. That class of apiarangene attributes. That class of aparists, who, like myself, are bee-hated, would have heard of them; adopted them; multiplied them; and before now, there would have been any quantity of stingless bees in the market. One word more as to the

STINGLESS BEE SOCIETY OF AMERICA.

Mr. Hawley may be thoroughly honest Mr. Hawley may be thoroughly honest and upright. From my slight knowl-edge of him, I am inclined to think that he is. But an "association" of which he is president, executive, and mem-bership, can hardly be expected to in-spire public confidence. If he were well known as a responsible bee-keeper; had these bees in actual possession; could state from personal experience. that they were angelic insects; and offered them for sale from his own apiary, the case would be different. As it is, it is proposed to try an experiment, it is, it is proposed to try an experiment, on an insufficient guarantee. Beekeepers have been swindled so often, that it is no wonder they have learned caution, and even become suspicious. With all my lack of faith, I would like to see the experiment tried, but I confess I do not see much likelihood of it, in the present shape of matters. If Mr. Hawley could go to Brazil, as Mr. Lones did to Cryma and Palestine on Mr. Hawley could go to Brazil, as Mr. Jones did to Cyprus and Palestine, on his own hook, import the harmless creatures, and then offer them for sale, the thing would be feasible. The mention of Mr. Jones reminds me that he has embarked in an enterprise which fills me with

# HORROR AND ALARM.

He has undertaken to import the big bee of Java, that awe-inspiring insect, about which I read a paper at the Chicago meeting of the North American Bee-Keepers' Association. I implored my fellow-bee-keepers to give that dreadful bee a "good letting alone" until I was dead and gone. That a fellow Canadian should be so cruel as to bring this fearful opis to my country, is indeed "the unkindest cut of all!" But Jones says he doesn't care if their stings are an inch long, provided they will gather more honey than others. He is not satistied with 250 pounds of honey per hive, and a prospect of \$10,000 profit next year. Covetous man! He will ceptainly find himself in the penitentiary or some other awful place, if he introduces into a civilized country like Canada, such a savage barbarian of an insect as the big bee of Java! He has undertaken to import the big

# THE WEEKLY.

I cannot close without expressing my gratification that the American Bee Journal has grown into a Weekly, and my hope that its success in that form may be even greater than that of its monthly predecessor.
Listowel, Ont., Jan. 15, 1881.

For the American Bee Journal.

# Notes by the Way-Side.

# H. L. JEFFREY.

I have been thinking for the past two I have been thinking for the past two seasons I would try to send you a report in the shape of "Notes by the Way-Side." Since I was appointed Vice President of the National Association, in 1879, I have devoted all the time I could spare in trying to give a little information to the loss him less was that formation to the box-hive bee-men that are within 20 miles of me, and I have picked up a few items that I think call for an article that will invite the altention of amateurs, novices and specialists to look out for some trouble, and the ists to look out for some trouble, and the cause I cannot determine, though I am satisfied it is not a fungoid growth. Mr. L. A. Pennoyer's letter, on page 3 of the AMERICAN BEE JOURNAL for Jan. 5, is what has caused me to mention the trouble now. It is not the regular foul brood, but, so far as I can learn, it is just as destructive in its tendency to depopulate a colony. The first symptoms shown are that nice combs of larvæ are to the casual observer suddenly nothing but empty cells, or even a comb well stored with eggs, and yet the colony keeps running down or de-

the lower side of the cell looks dirty, the lower side of the cell looks dirty, and if you look into the bottoms of the cells there is nothing to be seen, and yet every successive lot of brood will go in the same way. I cannot call it the regular foul brood, because it is never capped over; at least. I never knew if to live till capped over. I cannot ascertain the cause, though there are some evidences that indicate that it is the lack of vitality in the queen, and some that indicate that the larva starve for want of bee-bread. Yet none of these causes seem to be the originators of foul brood, neither does originators of foul brood, neither does this trouble seem to turn into foul brood so far as I have observed.

Another trouble that I have found.

and only in a low or black grade of hy brids, is that the brood is uncapped after the eyes are formed, and then they is that the brood is uncapped turn dark-eolored and are about one-third thrown out. This species upon close examination, shows a reddish-brown, dust-like substance at the ex-tremities of the thrown-out bees, that I

tremities of the thrown-out bees, that I think must be a parasite. After a while it turns into foul brood that is foul enough for anybody.

The dried-up brood I have had only in one of my own colonies, and that contained an imported queen; but they were cremated, and have left no taint behind them.

The first I ever saw of the bald-headed bees was 3 years ago, but the past season I have found plenty of them 18 miles from here, near the New York tate line, and nearly all the trouble with state time, and nearly all the trouble with brood that I have seen, has been inva-riably in the low grade of black hybrids. This is not guess-work, but I have watched close and in many cases.

and in many cases.

I would give you one cause for real fond brood, that I have traced out in over 50 cases, but this manuscript is now too long. Perhaps I may give it before long, if it is wanted, and its preventive also.

also.
Woodbury, Conn., Jan. 6, 1881.

[Anything new relating to foul brood, its cause, prevention and cure, is read with deep interest and we hope Mr. Jeffrey will forward the article at an early day.—ED.]

Dying by Wholesale.—Bees here are ring by wholesale. We have had 7 dying by wholesale. We have had a weeks of cold weather and there is no weeks of its being warmer. The prospect yet of its being warmer. The Weekly BEE JOURNAL is just splendid; it cannot fail to be gladly received. Success to it and its editor.

L. JOHNSON.

Walton, Ky., Jan. 18, 1881.

Well Paid.—I can assure you I am very much pleased with the Weekly BEE JOURNAL. I think I have been highly compensated for the money inted. You have my best wishes for American Bee Journal. Toledo, Iowa. WM. E. STRUBLE.

Toledo. Iowa.

No Honey last Season.—The past season yielded no honey. I fed my bees over \$30, worth of sugar syrup to keep them alive. I expect to lose many of them during this cold winter. I fed freely in the early part of October, and put them into winter-quarters the first week in November. I can do without honey but I do not want to do without the American Bee Journal.

Paniel Rider.

Fairfield, Iowa, Jan. 7, 1881.

Prevention of Swarming. - I was suc-Prevention of Swarming.—I was successful last season in preventing swarming. From 35 colonies in the spring I had but 6 swarms. My desire was to get more honey and less swarms. I have sold 1,326 lbs. of comb honey and have about 200 lbs. more, partly dark and some boxes not quite tilled out. Have used all we wanted in the family. Three of my colonies were queenless in May, from which I obtained no houey.

Severe Weather for Bees.—How our bees will come out of this severe winbees will come out of this severe win-ter, I do not know, but I fear for them. We had a poor season last year, especi-ally the latter part of it. Bees were strong in the fall and commenced win-ter with plenty of honey. I am much pleased with the Weekly—for me it is a necessity.

G. W. Jenkins, New Liberty, Ky., Jan, 8, 1881.

Tobacco Smoke for Bees.—I saw the assertion in the Western Rural that toassertion in the Wistern Rural that to-bacco smoke does not stupify bees, but alarms and causes them to fill their sacks; therefore, they will not sting. The truth is, that a common clay pipe. the truth is, that a common endy pipe, half-filled with tobacco, lighted, with a cloth over the bowl, and blown forcibly into the entrance of the hive, will cause the bees to fall from the combs and lie harmless on the bottom-board, as any bee-keeper can satisfy himself by one trial. It gives the operator time to take the frames all out and put them back again. Waterloo, Wis., Dec., 20, 1881.

Poisonous Wild Honey.-I do not see Poisonous Wild Honey.—I do not see why wild honey is necessarily poisonous any more than tame honey; the wild bees and the flowers are the same in both cases. My theory is, that the cause of wild honey being poisonous is owing to the fact that when a tree is cut and falls, it produces a sensation in the hive. often smashes combs, honey, bees, pollen and rotten wood all together, in which operation it is the nature of the bees to sting, depositing the powerful acid in the honey; then it is eaten and is quite liable to produce sickness, and is quite nable to produce siekness, and the stomach may be in such a state as to produce death, if enough of the poi-son is taken. We kept bees in Vermont, and our honey never made any one sick. A bee-tree was cut near by, and all who ate of the honey were sick. There was a great deal of argument made over it, but they finally settled the question satisfactorily to themselves by supposing the honey was gathered from kill-lamb.

L. MARTIN. Hesperia, Mich., Dec. 10, 1880.

Small Share of Honey.—My bees were in the best of condition to winter; plenty of stores and of line quality. were in the best of condition to winter; plenty of stores and of line quality. The bee keeper had but a small share of honey for last season's labors. I think the prospect is good for another year. Success to the Weekly BEE JOURNAL and our honey gatherers. Bethany, Ill. A. M. Rhodes.

Dysentery. —I am sorry to say that that fearful disease, dysentery, has visited our vicinity and destroyed more than half of the bees in the neighborhood; some loosing all. We have lost but 7 colonies as yet, but what the end will be we cannot say. We have every number of the Ber LUENAL from Luce 1878. we cannot say. We have every number of the Bee Journal from June, 1878, as neat as when received, but they are worth more than money to us, I could ot part with even one number.
Fineastle, Ind. MARY BROTHERS.

Honey Season in Pennsylvania. have the first two numbers of the Weekly and are very much pleased with it, and the prospect of getting such valuable information as the Journal always contains, just fresh from the authors, is alone worth the additional cost. It is agreable reading these long winter evenings. This shows progress winter evenings. This shows that deserves encouragement. that deserves encouragement. No telling but what a daily may yet be issued, and even progressive bee-keepers be connected by telephone with the exchange in the JOURNAL building. We had a very good season for honey and increased till July, but afterwards about as noor as it could be. as poor as it could be. We got about 200 lbs. of honey, and doubled our number of colonies. We now have 21 colonies packed in out chaff, 6 inches on all sides, and the bees covered with quilts and old sacks filled with chaff pressed tightly into the upper stories. We will have What I have sold comes to \$163.88, into the upper stories. We will have Bees have done rather poorly this year.

Some complain that their bees have done nothing, while others have done very well. Sneess to the Weekly Bee Journal.

T. Lashinook.
Waverly, Iowa.

The last their bees have about 2 inches and gable roof with venture of the meaning the cover the upper story may be nicely packed, while with the cap fastened to the cover it is more trouble and cannot be labeled to the cove be done so well. It is not necessary to state that we have severe weather, etc. Since the beginning of November our bees have had no fly, excepting 3 colonies which were out last week. The alightles which were out last week. The alighting boards and the snow around was considerably soiled, and some of the bees chilled and remained out. We have lost none yet and hope to get them all through, but won't whistle until nearer out of the woods.

W. H. STOUT.

Pine Grove, Pa., Jan. 15, ISSL

Bee Keeping in Texas,—I have received the first copy of the Weekly JOURNAL. It is very fortunate to be able to greet such a visitor once a week. I am much interested in bee-culture, an inner interested in bee-culture, especially in our State, for we have as good a country as there is on earth, for bees and honey. Very few have thought of it, beyond having some old guns in fence corners. I have the simplicity hive; the first movable frames I ever saw. I have also the first Italians I ever saw. I love to see the interest developing everywhere in this pleasant as well as profitable industry. I am determined to aid its progress every way in my power, and if all who take an interest would do the same, we would terest would do the same, we would soon become a power for good in this great land. This is a gloriously bright New Year's morning; the past 5 or 6 days have been very cold, the thermometer as low as 11- above zero—the coldest for 30 years. Bees have done well this year, God prosper us all, and gives us a planteous year. gives us a plenteous year.

J. E. LAY, M. D.

Hallettsville, Texas, Jan. I, 1881.

About Fertilization in Confinement.—Your correspondent, M. B., from Indiana, seems to think that he has sucdama, seems to think that he has succeeded in having his queens fertilized in his new fangled cage. I would be glad to know that it was a success, but like "blind Jack" I would "rather see it than hear tell of it." In the back Nos, of the JOURNAL some one claimed to have had enough fertilized by hold. to have had queens fertilized by holding them in his fingers, which I have thought might succeed if the queen could be made to open the vagina or could be made to open the vagina or spermatheca, either voluntarily or spasmodically. Suppose they were made to gape open the vagina, by the use of chloroform or some anaesthetic, say puff ball or some of Mr. Alley's tobacco smoke, say not enough to destroy life, but just enough to cause them to open up the parts; the drone, I think, can be made to do its part by first squeeze his head, and then let the pressure gradually extend back to the abdomen. Those that have never tried it, can learn some that have never tried it, can learn something; this is only thrown out as a suggestion for experiment. J. F. LOVE.

Cornersville Tenn.

Long Confinement.—Our bees have not had a flight since the first of Nov-ember. The thermometer, is 16 below ember. The thermometer, is 16-below zero. We winter in cellars here. I never knew a man to lose a colony if they had plenty of honey, and proper ventilation, in this country. Success to the Weekly BEE JOURNAL.

Harlan, Iowa. JOHN MCGINNESS.

Of Much Benefit .- I must have the Weekly JOURNAL. I hope I will get as much for the amount invested as I have for the past volume. The past year was I the amount of the Weekly, but I was benefited many times the amount besides the knowledge I have for next year's work. I began my apairy with the Journal, last spring, and by every number I revised my work, otherwise I would give the business up. I have 55 colonies, 43 in the celler, and t2 packed in planer shavings.

Cedar Falls, Iowa. A. J. Norris.

Homeless Swarm. - Two of my neighor's boys found a swarm of bees and about a half a bushel of comb hanging do a fence rail, about two weeks ag during our coldest weather. It is need less to say they were all dead. The comb contained considerable honeyveeks ago, It is need-

was something new to me, so I thought I would see if you ever saw or heard anything like it. C. HOLLOWELL. Dunreith, Ind., Dec. 25, 1880.

[We have frequently known swarms to settle after flying a long distance, and make considerable progress in comb building; apparently as though they had been disappointed in their selection of a home, and were keeping themselves busy until a satisfactory home could be found. The case you cite was probably similar, except that their delay was extended until after the storing of honey and depositing of eggs took place, when they were loth to leave and the early setting in of winter found them unprotected, and they perished. These cases are not frequent.—Ep.)

Errafa.—On page 2, column 4, of the Errata.—On page 2, commit 4, of the Weekly American Ber Journal, I was made to say that I returned the queen to the colony; I did not. Before the queen is expected to emerge, the cage is adjusted to the entrance of the hive, and remains there until the object is accomplished, when she immediately returns to the colony without aid. It takes but a few minutes for the bees to learn their passage and resume their work.

First Year's Experience.—I am highly pleased with the idea of a Weekly BEE JOURNAL; it looks like business, to get the JOURNAL weekly. I commenced with 3 box hives, last spring, I have 8 Langstroth hives in pretty fair condition—2 of them Italianized and 2 hybridized. This is the hardest winter I ever saw in this country by half. Six to gight weeks earlier them ordinarily to eight weeks earlier than ordinarily winter commenced in this latitude. We had S or 10 weeks of drouth last sum-mer—causing bees to be rather short of stores, I have had to feed and, but for buckwheat and the fall weed bloom, all buckwheat and the fall weed bloom, all my bees would have starved before winter came. We took no honey—many of the bees of the neighborhood have died long since, of starvation; one man has lost all his bees—they were all in box hive and "tree gums."—There are but very few movable frame hives in this portion of the country. If I can only be successful with my 8 colonies and get them through the winter, there will be a revolution in bee keeping in will be a revolution in bee keeping in this section. Men will try Bee Journals

and Langstroth hives, etc.
J. A. Burrow, M. D.
Santa Fe, Tenn., Jan. 17th, 1881.

Comb Foundation Machines.—I have read the article of Dr. Brown, in the American Bee Journal of the 5th inst., and as I do not agree with him. I wish to answer as follows:

1. He says that the Dunham machine is sold at the same price as the others; but I am assured that he does not know the price of every machine.

2. He says the Dunham machine is more difficult to make on account of its high side-walls. Had be the experience in making machines that I have, he would not say so, because the punch has only to be driven deeper into the rolls to create this slud. I do not make high side-walls on my machine, and I have good reasons for not doing so, which if Mr. B. wishes to know I can tell him.

JOHN BOURGMEYER.

Fond du Lac, Wis., Jan. 17, 1881.

[The above is a very curious lettercurious, because incomprehensible. We have read and re-read the article written by Dr. Brown, above alluded to, published on page 5 of our issue of the 5th inst., and cannot possibly give it the construction Mr. Bourgmeyer places on it. The Doctor's remarks are applicable to the cost of the foundation, and not the machine, and his eulogistic mention of it is endorsed by nearly all who have used it; he is too careful of his very high reputation to risk it on an unworthy commendation.—ED.]

CHICAGO, 11.L., JAN, 26, 1881.

K The Semi-Tropic California says "Our pospect for a honey crop in 1881. in Los Angeles, and vicinity, is good."

We have now obtained the copy of minutes of the National Convention of 1871. Thanks to Mr. A. F. Moon, of Rome, Ga., for it.

tse The " Bee Hive and Home Magaproposed to be issued by Mr. Crowfoot, is not to be issued now. Mr. Crowfoot says: "The enterprise is indefinitely postponed."

The editor of the Somerset, Pa., Democrat, speaking of the honey of Mr. H. H. Flick, of Lavansville, Pa., says it " equals California honey in color and excells it in taste," and that he has a large apiary on his farm near Lavans-

Fig. It would save us much trouble, if all would be particular to give their P.O. address and name, when writing to this office. We have several letters (some inclosing money) that have no name. Many others having no Postoffice, County or State. Also, if you live near one postoffice and get your mail at another, be sure to give the address we have on our list.

Mr. The weather in the North is still cold, but milder than it was in the early lillustration of a twig in bloom. part of this mouth. It has been colder all over the country than it has been before for years. In Texas it is reported Mr. W. Williamson, of Lexington, Ky., "The severe weather is breaking upfeeding very early."

Tast Sunday's Chicago Times contains the following item of news: "A pouch of registered mail matter of the papers for ISSI. first-class, which arrived in Chicago by a Lake Shore train on Wednesday evening, from Rochester, was found to have been cut open and robbed of valuables to an indefinite amount." These were registered letters and packages. containing money. We hope there were no letters in it addressed to us.

. . --- . .

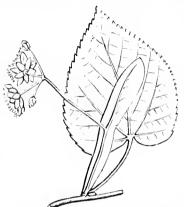

We have filled orders for onite a number of Binders for the Weekly Ber. JOURNAL. We put the price low, 30 per cent, less than any one else could afford to sell them, for we get them by the quantity at wholesale and sell them at just enough to cover the cost and postage, the latter being 21 to 23 cents, on each. We do this to induce as many as possible to get them, and preserve their Weekly numbers. They are exceedingly convenient; the Journal are sent with each one.

# The Basswood or Linden Tree.

Will you please state the habits of the basswood tree; its height, how long efore it will yield honey, and if it will flourish in this State. E. M. Gresham.

University of Va., Jan. 18, 1881.

Basswood or finden (Tilia Americana) is indigenous to a large portion of the North American continent: growing. often, to a very large size, and vieing with other forest trees in height. It is quite hardy, and grows readily and thriftily from the seed. We have heard of its blooming and secreting honey in six years after planting. The seeds should be sown in drills and enlighted

one year, then transplanted, setting from 10 to 14 apart each way. It prefers the proximity to water-courses, bottomlands, and gravelly soils in which water stands near the surface the whole season through. With these points borne in mind, and kept partially shaded until the roots and rootlets are well developed, we think it will flourish in your State. It is worthy of a trial, as it possesses a magnificent foliage, and is a great favorite with the bees when in bloom. We give on the first page a very correct

We will send sample copies to any who feel disposed to make up clubs for to be colder than for 30 years before. 1881. There are persons keeping bees in every neighborhood who would be in a letter, dated January 20th, says: benefitted by reading the JOURNAL. and by using a little of the personal inwe hope for good. We anticipate an fluence possessed by almost every one, early spring. Those of the bees that a club can be gotten up in every neighlive through the severe winter will need borhood in America. Farmers have had large crops, high prices, and a good demand for all the products of the farm, therefore can well afford to add the BEE JOURNAL to their list of

We have concluded to make the following offers for all clubs sent in before Jan. 31: For a club of 2, weekly, we will present a copy of "Bee-Culture;" for a club of 5, weekly, we will give a copy of "Cook's Manual," bound in cloth; for a club of 6, we give a copy of the JOURNAL for a year free. Do not performed. forget that it will pay to devote a few hours to the BEE JOURNAL.

😂 On Monday morning, express and mail cars, with all their contents, as well as four messengers, were entirely burnt up, in a railway accident near Elmira, N. Y. . . \_ . .

\$\text{\$\pi\$}\$ The Volume of the BEE JOUR-NAL for 1880, bound in stiff paper covers, will be sent by mail, for \$1,50,

Notices and advertisements inbeing always bound and handy for tended for the Weekly BEE JOURNAL reference. The directions for binding must reach this office by Saturday of at the present time of the non-effectthe week previous.

# "Compulsory Honesty."

We have received from Mr. Chas. F. Muth, of Cincinnati, O., the following or a selfish ambition to protect themcommunication, criticising the bill published in our issue of the 12th inst. under the above caption :

Compulsory honesty, if demanded on too broad a scale, will accomplish nothing, just like compulsory temperance or proposed by a house which is recognized by our business community as one of the largest adulterators in the country. They do not adulterate honey, of course, but they have to add a certain quantity of glucose in order to keep the honey from granulating; the trade demands it. So they stated, some time ago, that they had to add a certain quantity of trey had to add a certain quantity of commeal to mustard, in order to make it more palatable—but their mustard was pure. Like the French army, which was never conquered—only beaten.

was never conquered—only healen.

If oney has become a staple article of great importance of late years, and has an important future. It can be shown of sufficient importance to our legislators to pass a law exclusively for the pro-tection of honey; and it is my opinion that we shall accomplish nothing with a petition for universal protection.

Let us draw up a petition for the protection of honeyalone, setting forth the great growth of its production of late. and the prospects for its future. make it plain to our representatives how necessary to a healthy development of the production of honey is the pro-tection of the law against its adulteration, etc.

If we draw out a petition (or resolutions) in good style, I am certain that the representatives from Ohio will use their best endeavors to have a law passed in our favor. Our friends in other states, exercising a similar bearing on their respective representatives, will an the matter considerably. Would it not be well to petition our State Legisla-tures as well as Congress?

Cincinnati, O., Jan. 17, 1881.

We care but little with whom the bill referred to originated, so that the amendments we suggested (or similar provisions) to make it operative and to cover the public wants be incorporated The mere draft of the bill, as published in the American Grocer, did not seem to cover the whole ground, but with proper effort on the part of bee-keepers and others it could easily be made to cure the grievous evils complained of. We must admit we are unable to comprehend the analogy between compulsory honesty and compulsory temperance or compulsory religion. The first would compel the dealer to give the purchaser an honest equivalent for his money, and anything else would be deceiving an ignorant or unwilling purchaser. The second would compel a dealer to refuse a customer what was called for, presupposing the purchaser not to be a free moral agent. Compulsory religion bears no closer comparison, as it would be an attempt to compel certain phases of conscience, without reference to acts

Petitions have been drawn up, and presented, and "pigeon-holed" time and again providing exclusively against the adulteration of honey. And we are not prepared to assert, that were a special law enacted it would help matters. We have heard of nothing good resulting from the special law in Minnesota, New Jersey and Kentucky. So effete is the law in the latter State, that mixed "strained" honey can be bought in any quantity and at many stores in Louisville at the present time—so we are informed.

In Illinois we have an apt illustration iveness of special laws. The dairymen, as the new one.

feeling sorely the evils indicted upon them by unscrupulous counterfeiters. with an honest but short-sighted zeal selves alone, succeeded in procuring the passage of a stringest special law proteeting dairymen and dairy products. Not only has the law proven ineffectual, but the evils have augmented to a magcompulsory religion. I feel that way a mitude which is truly stupendons, and little more, perhaps, because that law is mow the stuff is in the majority. Humnow the stuff is in the majority. Hundreds of families in Chicago at the present time dispense with butter, because they know not what nor from whom to buy. Some time ago a paper was circulated among business houses, and several thousand dollars were subscribed with which to employ legal talent and prosecute the offenders, and-there it rests. Last week many of our business and commission houses signed a paper oledging themselves not to traffic in the stuff; but it will probably effect nothing but lessen competition. And still not a tremulous fear quivers the nerves of the guilty manufacturers, nor do the pangs of remorse rob them of a moment of refreshing slumber. As well pass a special law making it a crime to steal money or other valuables in small parcels, but classify the plundering of communities among shrewd business or financial operations. We need no law to prevent honey

adulterations, unless it will prevent sugar and syrup adulterations, with which we come directly into competition. We have no moral right to ask protection for our pure commodities, unless we accord the same protection to other honest producers; nor is it in accord with the theory of democratic government, to legislate class or special laws to punish crime. We can see no remedy but a general law, simple and practical in its enforcement. Let the informer be repaid out of the fine for any trouble or expense he may incur. Make it an object to the defranded customer to prosecute the swindler, and he becomes an effective agent in enforcing compulsory honesty.

Since the above remarks were put in type, we notice the following article from the pen of Mr. F. J. Emery, in a late number of the *lowa Homestead*, and as it bears so directly upon the subject under discussion we cannot refrain from copying it:

To point out that which has been done dsewhere, in a parallel case, might be done here also as a remedy. About 30 rears ago in England a law was passed relative to adulteration of food and etc. It has been very strictly carried out. The substance of the law is that no article shall be sold under a false name. For instance a man may sell chicory, but he must not mix it and call the mixture coftee. He may self-olcomargarine, but he must not call it butter; and so of but he must not call it butter; and so of the endless variety of items used as lood. A public chemist is appointed whose duty it is to analyze what is brought to him of suspected articles bought at the retail shops, and if adul-terated, a State prosecution before a justice summarily disposes of the case by a tine. A light line for the first of-tence—heavier for a second conviction, and the shop and its owner are adverand the shop and its owner are advertised in the papers as having such and such articles adulterated, and particulars of analysis are given. If the retail dealer pleads that he bought the adulterated retides in small fath from the terated articles in good fath from the wholesale dealer he is told "the public must be protected, and you have your remedy against the wholesale dealer."

When changing a postoflice address, mention the old address as well

# Experience with Comb Foundation.

Seeing of late that a number of apiarists give their experience in the use of comb foundation, and that their verdict is in favor of that made on the Dunham machine, will you allow me modestly to give my experience with foundation for the benefit of those that have yet to

commence its use.

In 1878 I used 50 lbs, of foundation made on the Root machine, received from a manufacturer in the State of New York, which the bees used readily

Aew Fork, which the bees used readily and to my satisfaction.

In 1879 I used 103 lbs. made on the Root machine, received from a manufacturer in Ontario. It pleased me and

the bees well.

In 1880, I used 175 lbs. (out of 200 lbs.) In 1880, I used 175 lbs. (out of 200 lbs. purchased) made on the Dunham machine, that did not please me. Contrary to the testimony of others, it was not received by the bees so readily, and it did sag very much. The high walls did not come with the foundation, as you will see by the sample enclosed. It was will see by the sample enclosed. It was purchased in Michigan, from whom I will not now say, as it would not be a good puff for said firm.

brood chamber, if used about 6 feet to the lb., made of pure wax. Woodstock, Ont. J. B. Hill.

Woodstock, Ont.

[We are under obligations to Mr. Hill for enclosing the sample of objectionable foundation, as it gives opportunity for intelligently commenting upon what for intelligently commenting upon what has probably caused some of the differences in experience with Dunham fountialian queens is no longer advisable as dation. We say objectionable foundation, for if the sample sent is a fair specimen. leaving out the possibility of adulteraseen and used foundation made on five ance of wax in the sides, where the bees foundation.

In this connection, we will take occasion again to impress our readers with the desirability of purchasing supplies cle is sold for the least money, is not most plausible story. The advertisewill be found in our columns.—Ep.1

be successful in removing bees from the cellar for a tly?

bees while in the cellar, if the entrance is left unobstructed?

3. Is it advisable to cover the entrance

with wire-cloth while in the cellar QUERY.

St. Paul, Minn., Jan. 15, 1881.

1. When the weather is warm enough that bees can fly from the hive and return, without dropping on the snow.

2. No: but they frequently come outside to die.

3. No; never.

Sample copies of the Weekly BEE JOURNAL will be sent free to any names that may be sent in. Any one language quoted above from our issue intending to get up a club can have of the 12th inst. sample copies sent to the persons they names to this office.

# Do we Want Facts?

The Rev. A. Salisbury, in the American Bee Journal of Jan. 12, refers o a resolution brought before the Cincinnati Convention, which was tabled very promptly without discussion, and proceeds to deliberate on the question n a most reckless manner, as though hat "high-toned" body had not said by that "nigh-toned body had not said by their action, We do not want this matter discussed. Not only does he do this but he incites others to the same folly, for he says, "We want to hear from the leading bee men of the country on this subject.

Mr. S., what do you mean by such suicidal disloyalty to the great bee-keeping interests of this country? Do that we have been to so much trouble in the two so were that we have been to so much trouble in the two so were the two so what do building up? I fear you do. What d you think that Convention "sat down" on that resolution for? Perhaps it was not the proper place to discuss such issues. Is it facts we want?

11. R. BOARDMAN.

East Townsend, O.

Referring to the above communica-I think foundation a success for the tion, which savors more of sarcasm than eandid discussion, we copy the resolu-sion, but most of it being irrelevant, tion alluded to, from the BEE JOUR-NAL's report of the proceedings of the National Convention, second column page 520, November number, 1880:

Mr. Boardman moved, as a test of the

an improvement of our present race of

It is difficult to imagine how a Contion in the wax, we object to it for use vention, composed of many of the most in the brood chamber-1st. Because it is intelligent and most progressive beetoo light in weight; 2d. It is minus the keepers of America, could do otherwise Dunham side-walls; and,3d. It was not than table such a resolution, when anade on a Dunham machine. We have offered, without supplemental explanation, to test the sentiment of its mem-Dunham machines, and the same gen-bers. In fact, even though as individeral characteristics were prominent in uals fully coinciding in the gist of the each, viz: Thin septum or base: high, resolution, it could not adopt that, prominent side-walls, and preponder- alone, without stultifying itself by discouraging one of the possible means of can use it most readily and rapidly. Of further improving our stock, through course we do not know who Mr. Hill the importation of the most superior purchased from, but we do know the strains of Italian queens—if there are sample sent to this office is not Dunham superior and inferior bees in Italy, as claimed by the breeders there, and, as we are free to admit, we fully believe.

The insimuation that the resolution was tabled in the interest of the imfrom honest dealers. Because an arti-porters, is wholly without a shadow of foundation, and is unworthy of Mr. proof that it is the cheapest; any more Boardman himself. We venture the than that honesty always dictates the assertion, that not one in ten of those who voted in the affirmative have ever ments of several responsible dealers imported a queen from Italy direct for traffic; and not ten per cent. of the few who have can boast of clearing one Questions.—1. When snow covers the penny as profit, if their sales were made earth, what must be the temperature to at present popular prices. at present popular prices.

We reiterate, that "while we believe 2. Will bees cleanse the hive from dead the intelligent and discriminating beekeepers of America have succeeded in breeding a strain or strains of bees equal, if not superior, to any to be found in Italy, we would not discourage any from importing if an improvement is possible....We do not doubt there are many fine queens bred in Italy, but we do believe none are better than our by its action in tabling the resolution be construed as a more positive endorsement of the system of indiscriminate

desire to interview, by sending the course, it is. But we want all of them, as a representive body of bee-keepers. The "high-toned body," as Mr. Board- 1s it facts you want?—these are facts.

man sareastically alludes to the Conactive member, "sat down" on the vention, which is to be held at Andover. resolution because it did not properly. O., on Tuesday and Wednesday, Feb. 8 cover all the ground. The first and second of the series of resolutions day, the 8th, we have engaged to deliver offered by Mr. Hayes did cover all the ground, were freely and fully discussed. There being a large number of beeand our report says "passed unani- keepers in that region, we expect the mously" upon a vote being taken, inceting will be very largely attended. Compare, carefully, the resolution All interested will please notice the date offered by Mr. Boardman with those adopted unanimously by the Convention and the cause for complaint will remain undiscovered, unless it is because the first of Mr. Haves' resolutions specifies a sole reason why importations should be encouraged, if at all, and Mr. Boardman's resolution left that to inaplication.

"Do we want facts?" If so, refer to the page above cited, and it will be observed the resolution was not "tabled very promptly without discussion.' Our reporter gave some of the discuswas omitted to save space.

It is evident Rev. Mr. Salisbury's communication was read under a misapprehension. His many years' experience with imported and home-bred Italians have not been thrown away; nor have his observations as a progressive bee-keeper failed to develop queens, in his own apiary superior to their imported mothers. We are confident had be been in attendance at the Cincinnati Convention, his vote would not have broken the harmonious unanimity with which the following resolutions were adopted:

Resolved, That the importation of pure Italian, Cyprian and Holy Land bees into North America, ought to be encouraged for the sole purpose of add-ing new and different strains of blood to that we already have.

2. That the strain of Italian blood we now have has reached a higher standard of excellence than is to be found in the native home of the Italian.

That queens reared from pure selected home-bred Italian mothers, should command at least as high a market value as those bred from imported mothers, where pure Italian stock is the

For Mr. Boardman, personally, we have the highest regard. We listened with much interest to many of his remarks, and certainly he cannot complain of any want of courtesy, either on the part of the officers or constituent members of the Convention. That he takes an honest pride in the advancement of scientific apiculture we do not doubt, and we fully sympathize with him in his estimation of the superiority of American-Italian bees; but we cannot believe with him that the Convention endeavored to shirk any expression of opinion, nor that the Convention, or a majority of its members, failed to give any matter brought before it proper consideration. That all questions deliberated upon were settled with the precision of inspiration we do not claim; but all decisions were rendered best." And certainly, the Convention, through honest motives—the talent and experience represented were of a high given above, did nothing which could order, very far above the conventional average. We have attended many beekeepers' Conventions, and other deimportation than can be found in the liberative bodies, but never one superior to the Convention which assembled in Cincinnati last fall; and it is a source "Is it facts we want?" Yes; of of honest pride to be able to refer to it

**©** We have recepted an invitation to vention, and of which he was a very attend the Ashtabula County, O., Conand 9, 1881. On the evening of Tuesa public lecture on "Bees and Honey." as it has been changed.

British Bee Journal.

# Congress of Bee-Masters at Cologne.

COL. G. J. PEARSON.

The occasion was somewhat more than ordinarily interesting, for it was the twenty-fitth anniversary of the Con-

The proceedings commenced on Monday evening by an unofficial meeting of those who arrived from all parts of Germany and Austria to take part in the Congress. Among them were many who have a European reputation as beekeepers, and I may especially notice the great Dzierzon, the Baroness Von Ber-lepsch, Herr Vogel (author), and the Pasteur Rabbow, of Hohendorf in Pomerania.

The Exhibition opened on the morn-

The Exhibition opened on the morning of Tuesday the 7th, and resembled very much all exhibitions of the same description. If I may offer criticism on it, I should say that practical utility was not sufficiently kept in view by the greater number of exhibitors, who rathor sought to eatch the eye by the attractiveness of there articles. I may mention with exhibition that two out mention with satisfaction that two out of three of the exhibitions which gained silver medals (of which only three were awarded) were made up largely of articles which had at least a portion of their origin in England, Mr. Xeighhour having carried off one of them for an excellent collection of apicultural instruments and super honey, and Mr. Dennler having also a silver medal awarded to him for a dozen of Mr. Abbott's honey-boxes magnificently filled, and an extractor, the idea (though not the extractor, the idea (though not the mechanism) of which was borrowed from that of Mr. Cowan, which gained a prize at London last year. I shall refer to this extractor hereafter. For the rest, there were some well stocked hives of Cyprians and Italians in the courtyard, with some well-made portable hives for transporting bees or ancens from place to place. There were huge glass bells, nearly two feet high, well glass bells, nearly two feet high, well filled with comb, very pretty to look at, but not half so practically useful as our honey lookes. This, indeed, the jury fully recognised in their awards to Messrs. Dennler and Neighbour. There were also some ingeniously arranged devices in comb exhibited by Pasteur Rabbow, the bees having been made to build into moulds or shapes, which were afterwards detached, leaving the shapes of comb, like shapes of blanc mange, on a dish. There were also some capital masks, plenty of good comb-foundation. were also some capital and a number of hives, the prices of which ranged generally from seven to seven to shillings, a few fancy hives being higher in price. The stock of honey and mead in jars and bottles was very large. All this was, however. nothing more than may be seen at any bee show.

The important part of the proceedings the re-unions, where papers were md speeches made. The first of read and speeches made. these commenced at 10 a.m. on Tuesday, and lasted till 2 o'clock. It was opened by the Burgomaster, who in a short speech addressed the meeting, expressing a hope that the fiftieth Congress might be an international one, as there were few countries which now did not take some interest in bee-keeping. Then admidst the applause of the whole admidst the applause of the whole meeting, the delegate of the Minister of Agriculture and Commerce called up Herr Schmidt, of Eichsteid, who is the permanent Vice President of the Congress, and after complimenting him, decorated him with the order of the Crown, sent expressly to him by the Emperor.

The real business of the meeting then began, Dzierzon, who was most warmly study and watching, as well as practical—considerable experience. Thave come to application, if we would arrive at be very fond of these small frame hives, Herr Schzen, the editor of the Hanover—image failed to send results worthy of the end at which we which are so handy for storing and Bee Journal, replied to him: "We are the above notice.

strive. "What we know as yet," he exclaimed, "are like a few shells pieked up by a child on the sea-shore, which give but little idea of the wealth that

the sea contains."

Herr Vogel, whose book on the bee was rewarded with the annual gold medal of the Congress, followed next, taking up the question of a uniform or standard size of frame for all Germany. This has been long discussed, and has resulted in a gradual diminution of the size of frame. The time was thought to have arrived for definite The time action, and the size of frame was, after long discussions in the Congress, finally fixed at 23½ centimetres (or 9 inches) broad, with a depth of 36 centimetres or 15 inches) for the body of the hive. divided into two frames, each 18 centimetres (nearly  $7\frac{1}{2}$  inches) deep. This hive, however, admits of being built up to any height the amount of honey-gathering justifies. There are usually two rows of ten to twelve frames, or three rows of eight frames, one above the other, in each hive, making from twenty to twenty-four frames of the above size in each hive.

You are aware that in the German hives the frames always stand across the entrance, not at right angles to it. In this principle they exactly resemble Mr. Abbott's Combination Hive. There was only one German hive in the exhibition which had its frames at right angles to the entrance. And here I may mention a Swedish hive which resembled very much one of Mr. Abbott's Combinations, and which was furnished with a division-board frames to be put back from the entrance There was a tunnel leading from the entrance to the division-board giving ingress and egress to the bees, as for the ventilation of the hive; the for the ventuation of the have and space between the end of the hive and the division-board was then filled with chaff well rammed home. This seems to me a capital idea for keeping bees warm in winter.

It is no doubt a great advantage in Germany that practically one size of frame is adopted by all bee-keepers in all parts of the country. I am myself strongly impressed with the practical utility of the German hives. I have this summer been working very much with some which are known as the Baden or Black Forest hives. They bacen for black Forest filtes. They seem to me to present some very great advantages, both in regard to manipulation and supering. I am inclined to think that bees also winter very well in them. First, as regards manipulation. their. I first, as regards manipulation, the frames being drawn out by a pair of strong pincers from the rear of the hive, a small puff of smoke easily drives the bees downwards to the front, and in this way I really cannot remember ever having been once stung in opening a hive, which I have been doing lately every day; then the frames have only a every day, then the frames have only a small bearing at the ends, and are very easily detached from the propolis. Thirdly, the brood is invariably found in the front, and notably the lower front of the hive. In this way, for extracting you may take out the eight upper and four lower frames from the rear, with the almost absolute certainty of finding no brood in them. The frames being of small size are not at no brood in them. The frames being of small size, are put at once into the extractor, the honey is taken out, and the frames are replaced in the hive without any derangement of the brood or anany derangement of the brood or annoyance to the queen. Then for supering the narrow hive seems to concentrate the heat and send it into the supers, which the bees take to at once, while the broad while the broad shallow frames of the Woodbury would seem to fail in this particular. I can only say that two Alsatian gentlemen to whom I gave a Alsa gentlemen to whom I gave a number of Mr. Abbott's excellent sectional supers, have been showing me magnificently filled honey-boxes all the summer from their Baden hives, while I never have been able to get a bee to go into mine except for promenade purposes. I am disposed to think, too, that bees winter better in a deep narrow hive. By leaving them a certain num-ber of frames filled to all their depth, the bees need never change from frame to frame, but always keep near their food; and so it comes to pass that after considerable experience. I have come to be very fond of these small frame hives,

I would now add a few words on Mr Deunler's extractor. It was exteriorly the ordinary form, the motive power ing—placed—below the—body of the being placed below the body of the machine, and the center pivot turning in a socket below all; so that all the weight of the frames in the interior rested on the center pivot, and all straining was avoided. The eages for containing the honey combs for extraction are raised about 6 inches above the bottom of the receptacles so as to allow of honey being ex-rawing it off. The of at least 25 lbs, of honey bein tracted without drawing it off. whole of the appratus for turning is very solid and well made. The cages or receptacles for the combs are three in number, forming a triangle inside the receptacle; and this, I think, is its only fault, for with three frames there is no counter-balance on the pivot, and this must eventually cause an uneven and wobbling motion. It could be as easily made with two or four cages, and it would then be better; otherwise it admits of the frames being reversed like in Mr. Cowan's extractor, which is done by lifting each frame up about a quarter of an inch, turning it, and letting it drop into its place. This action is ex-ceedingly simple, takes no appreciable time to put in motion, and is not exposed to any chance of derangement.
As the machine exhibited has extracted nearly a ton of honey this year, its effi-ciency may be said to have been thoroughly tested and established. It was very greatly admired and praised by Dzierzon, and many other experi-

by Dzierzon, and many other experi-enced bee-keepers.

Among other subjects of interest from a practical point of view discussed by the Congress, was that of the use of perforated zinc as a queen-excluder.

This was introduced by Herr Gubler, who very clearly explained the great results which might be obtained by the use of it, in reference to the checking of swarming and the production of honey. Several bee-masters followed honey. Several bee-masters followed on this subject, saying that perforated on this subject, saying that perforated zinc was changing the whole system of apiculture, and the principles on which it was conducted from a scientific point of view. It may be added that the sale of perforated zine at the exhibition was or perforated zine at the exhibition was very large, almost more than that of any article. The holes are the same depth as ours, but have a greater breadth, at least one and a half to one of ours.

Professor Donhoff read a very in-teresting paper on the physiology of the teresting paper on the physiology of the bee, which was warmly applanded. Herr Frey, of Murenberg, did the same in reference to foul-brood, which he treated ably. Herr beichart, the Presi-dent of the Society of Apiculture in Hesse, read a paper on "Wintering Bees," the chief practical hint I gained from which was, that it was well not to leave edge honey in a hire for winter. leave colza honey in a hive for winter, as it crystallised very readily in the hives, and was not made easily available to the bees when in that condition. Herr Schzen spoke on the introduction of Italian and other foreign queens. He appeared to think that the chief advantage gained was the infusion of fresh blood into an apiary, and that this would be as readily effected by any other exchange of queens not necessarily of another race

The next Congress was then settled to take place at Erfurt in 1881; and either at Buda-Pesth or Frankfort-on-

e-Maine in 1882. There was another point of interest brought out in the discussions. You are perhaps aware that in Hanover, where there is an immense trade in exported honey, the practice is to destroy one-third of the hives every year, and take all the contents. This practice is justified by the people on the ground that they have too many colonies, and that they have too many colonies, and that they would be over-stocked with bees otherwise. In fact, they say that in a good year each colony will give three swarms and 100 lbs. of honey. Moreover, they say, by constant renewal of the combs, they avoid foul-brood, and have a much longer and finer race of bees. Pasteur Rubbow violent attacked the whole system as heing cruel. of bees. Pasteur Rubbow violent at-tacked the whole system as being crue!

manipulation. The only modification 1 not cruel, but what are we to do with should like to make in them would be our bees? We have 600,000 colonies the adoption of the quilt in winter.

I would now add a few words on Mr. gladly drive the bees, and sell them to you for a mark and a half (eighteen pence) each colony."

It is a question for our enterprising

bee-merchants whether it might be profitable to purchase bees in autumn at this price, feed them for winter, and sell them in spring. It may be observed that Pastenr Rabbow was right, and that by using frame hives and checking the laying of the queen by the use of perforated zinc dividers, the number of swarms might be diminished, and the income of honey increased in propor-tion. The hives used in Hanover are tall conical skeps, with the entrance near the summit

The show remained open and the meetings continued daily till Friday when the prizes were given, the gold medal going with universal applause to Herr Fred. William Vogel, for his recent work on bee-culture: Mr. Dennler and Mr. Neighbour, and one other, receiving silver medals; and many others diplomas of merit.

So ended a very interesting visit, during which I visited also the Industrial Exhibition at Dusseldorf. Perhaps the Exhibition at Dusseldorf. Perhaps the most interesting part of the exhibition was the pleasure and honor of meeting renowned bee-keepers like Dzierzon and the Baroness Von Berlapsch.

Nancy, France.

# Central Michigan Convention.

The Central Michigan Bee-Keepers' Association met in Convention in the Pioneer Rooms of the State Capital, at Lansing, Oct. 7, 1880. President Ashworth being absent, the forenoon was occupied with informal discussion.

At 1 p. m., Vice President D. R. Cole of Livingston, was called to the chair, and the Convention proceeded to business. The President delivered a short and spicy address on the subject of honey-producing and gave some of his observations during the season. His remarks led to a lengthy discussion of

the subject of wintering.

The topic of foul brood was next considered, and as it was reported to exist in the adjoining counties, it awakened much interest.

Prof. Cook said it was really terrible, He advised all not to buy bees or

and that none of us knew its effects. at a distance; if we did, it might bring on our ruin.

Vooice. What is the remedy?

A voice. What is the remedy? Prof. Cook. Immediate destruction of bees, hives and honey. Mr. Wood, of Grand Ledge. How do you do it?

Take the hive and con-Prof. Cook.

tents out in a field and build a bonfire.

Inquiry was then made about the Holy Land queen.

Prof. Cook said she was very prolific; that she laid 4,000 eggs a day by actual count, and that all of the workers were

uniform and very gentle.

Mr. Waldo, of Grand Ledge, said he ohtained a daughter of the Holy Land queen, and crossed her with Italian drones, and thinks he will like the cross

for their quietness.

Prof. Cook gave a few incidents from the letters of Frank Benton, which both annused and instructed the members present.

Time was then given for the examina-

The was then given for the examina-tion of the supplies, hives and fixtures. The attendance was large and the meeting passed off pleasantly. On motion of Prof. Cook, the Secre-tary was instructed to return thanks to the Superintendent of State Property for the use of the hall, and the attention for the use of the man, and somethe Convention received.

Adjourned to May 5, 1881.

GEO. L. PERRY, Sec.

The Rock River Valley Bee-Keep-rs' Association will hold their annual meeting at Monroe, Ogle county, Ill., on Feb. 8, 1881. The weather was such Feb. 8, 1881. The weather was such that our Secretary was not at our last meeting and our Secretary protein having failed to send in his report, I send the above notice.

A. RICE, Pres.

# What the Press says of the Weekly.

The following notices by agricultural papers will show how the Weekly Bee JOURNAL is received by the Press, turist, They have our thanks.

The American Bee Journal comes to us this week in a new form, and is the more welcome, since it has become a full-grown weekly. Twenty years ago it was started as a monthly and has ago it was started as a monthly and has "stood the storms of journalism untinchingly," and now starts out as it should have done long ago—a weekly. We heartily recommend it to our readers.—Patrôn's Guide, Boyd Sta., Ky,

T. G. Newman, editor of the BEE 1. G. Newman, editor of the BEE JOURNAL, informs his readers, that the bee-keepers' industry has grown to such importance that it now demands and will sustain a weekly publication devoted exclusively to its interest. What a stride in this in the last decade, when continuationly from comparable lawned. a stride in this in the last decade, when comparatively few persons had learned enough about the business to lay aside the old box hive and bee-gum for the movable frame hive. The world moves, however, and it is no uncommon thing to hear of apiarists shipping tons of leaver to market the medical of ref honey to market, the product of not more than a hundred hives,—Kansas

That excellent periodical, the AMER-ITAL EXCEPTION THAT IS A SECTION OF THE ASSECTION OF THE

The American Bee Journal is decidedly the best journal of the kind published. Every man interested in bee raising should take this journal.— Journal, Berlin, Wis.

If you want to know anything in regard to bees, take the BEE JOURNAL. Its pages are replete with information relative to apiculture, and its bright face and tasty make-up commend it to the public at once.—Ensign, Moulton,

The AMERICAN BEE JOURNAL, edited by Thomas G. Newman, Chicago, appears for 1881 as a weekly. It is the oldest bee journal in the country, and worthy the support of all bee fanciers.—

Home Journal, Louisville, Ky.

The American Bee Journal comes The AMERICAN BEEJOURNAL comes to us now as a weekly, and what has heretofore been the leading monthly bee paper, now becomes the leading apicultural weekly, as it is the oldest, in the Union. As it aims to give all the news respecting inventions and improvements. quarters of the globe, its weekly visits cannot but prove valuable to all who are interested in bee culture.—Farmer, Denver, Colo.

The American Bee Journal, for twenty years, the leading monthly in America, devoted to apiculture, now becomes a weekly under the management of its veteran editor Thos.G. Newman, Chicago.—Plain Dealer, Cresco, Lower Chicago.—Plain Dealer, Cresco, C

AMERICAN BEE JOURNAL. doubtless the best periodical in the country, or in fact the world, which is devoted to the interests of bee culture. It has now been changed to a weekly.—

Times, Bellow's Falls, Vt.

The American Bee Journal, here-The American Bee Journal, here-tofore the leading monthly bee paper, becomes a weekly in 1881. It is the old-est apicultural journal in America, and is the first and only weekly in the world devoted to bees and honey. We shall take occasion to copy from its very in-teresting columns occasionally.—Eva. Chautauqua, N. Y.

The American Bee Journal, heretofore a monthly, becomes a weekly in 1881. Those of our readers who wish the best bee journal will do well to subscribe for this one.—Pulaski, N. Y. De-

The initial number of the Weekly MERICAN BEE JOURNAL is before us The change from a monthly to a weekly is a great improvement, and everybody interested in bees ought to have it. It contains even more than its usual amount of interesting reading matter. -Eagle, Union City, Ind.

The American Beelournal is now published weekly, and is full of news about bees, honey, and other good things. No farmer who has bees should try to do without it .-- Western Agricul

The American Beedovanal comes to us in a new form. Heretofore a monthly, it appears weekly and will continue to take a lively interest in all continue to take a fively interest in an wise efforts looking to the advancement of the art and science of bee culture. We predict for it success in its new form, under its enterprising editor. New Bedford, Mass., Standard.

The American Bee Journal is the The AMERICAN BEE JOURNAL is the oldest periodical published in America, devoted to the scientific management of the honey bee. Every person who keeps bees should subscribe for the above named journal, and see the progress that has been made in the management of bees.—Latrobe, Pa., Jdvo-

The BEE JOURNAL is the oldest api-cultural journal in America, and is the first and only weekly in the world, de-voted to bees and honey. We should like to see every one in Hobart who owns bees take it.—Journal, Hobart, hol

The December number of the AMER-ICAN BEE JOURNAL closes the twentieth ican Bee Journal closes the twentieth year of its prosperous and useful existence. So prosperous has its career been that its enterprising publisher will celebrate, by hereafter issuing this publication as a weekly. This will commence a new era in bee journalism, and it cannot be entrusted into any hands with greater certainty of success than with Mr. Newman.—Standard, New Bedform Mass. with Mr. New Bedforn, Mass.

The American Bee Journal, published by Thomas G. Newman, at Chicago, which has heretofore been issued monthly, will be twenty years old Jan-nary 1st, and will from that date be is-sued weekly. It is exceedingly valu-able to bee keepers.—Iowa Homestead.

The American Bee Journal is the standard authority on the eare of bees, the sale of honey, etc.—Local, Silver Creek, N. Y.

The American Bee Journal, the leading and truly valuable publication now makes its appearance as a weekly instead of a monthly. The initial number is now before us. The monthly has been recognized as the very highest authority on apiculture for upwards of twenty years. It is published by Thos. G. Newman, of Chicago, whose reputation as a successful bee culturist is well known in this country and across the known in this country and across the sea. To every one interested in apiculture, we say subscribe for the AMER-ICAN BEE JOURNAL.—Sentinel, Carlisle,

The American Bee Journal twenty years old, and stands at the head of American journals devoted to the bee interests.—Farmers' Review bicago, Ill.

Intelligent bee-keepers will be glad to know that the American Bee Jourto know that the AMERICAN BEE JOUR-NAL, the first paper established in this country, especially devoted to bee enture. (founded by the late Sannel Wagner of good memory) is, with the beginning of the new year, to be published as a weekly. Every progressive beekeeper should have this paper.—Home Farm, Augusta, Maine.

The American Bee Journal, heretofore the leading monthly bee paper, becomes a weekly in 1881. It is the oldest apicultural journal in America, and est apicultural journal in America, and is the first and only weekly in the world, devoted to bees and honey. It has been published for twenty years, and its old patrons, to whom it has long been a pations, to whom it has long been a guiding-star, as well as its thousands of new readers, will together hall this new departure of the BEE JOURNAL with joy.—Patriot, Concord, N. H.

The American Bee Journal is the The AMERICAN BEE JOCKNAL is the leading periodical on bee-culture of the United States. It is neat, typographically and otherwise, and is edited by a gentleman who understand his business. We wish it abundant success.— Patrons' Guide, Ky.

# CLUBBING LIST.

We supply the Weekly American Bee Journal and any of the following periodicals, for ISM, at the prices queted in the last column of figures. The first column gives the regular price of both:

#### Hive and Section Making.

JAMES HEDDON.

I choose the above subject knowing that it is a practical one, and one of much interest and importance to beekeepers. I shall state only what has been my experience and observation. You will bear in mind that I speak from my side of the question, and that I am aware that I may be mistaken in many points, yet I believe that any one's honest onlyions formed from long experience. est opinions, formed from long experience and close observation, must in the main be of value to some readers.

#### LUMBER FOR HIVES.

LUMBER FOR HIVES.

Here we have nearly all the kinds suitable for their construction—pine, basswood and whitewood. I supposed for years that pine was the most durable of these woods, especially if exposed to the weather without paint. Closer observation has convinced me that whitewood is superior to pine for endurance, whether painted or not, and also that it takes and holds paint much better, because the oil does not soak into the wood as it does into pine, but remains outside and dries with the paint, into a perfect gloss. In regard to painting, the same may be said of basswood, but it decays readily if not painted. Whitewood and pine decay yery differently—whitewood all on the surface, pine not so at all, but through-and-through the board in streaks. Basswood makes a hive unexcelled, if always kept painted. All these woods are good enough, and I do not hesitate to use any and all of them; the difference is so small I do not consider it, as I always keep everything well painted.

equal to the cheap mineral paints. Of these the Venitian red stands at the head. Next, the French yellow ochre. This is the paint I use for hives, rather than the red, on account of its color be-ing lighter and not so heat-absorbing. For winter boxes I use the red, for reasons above given.

#### CONSTRUCTION OF HIVES,

or what hive to use. This has been the question of questions with all beginners. I prefer a top-storing hive exclusively. To me, an argument in favor of sidestoring is an admission that the shape or construction of the hive of the advocate, is faulty. The Langstroth frame seems to me to be the hest size and shape to give us the most advantages. I differ with many as to the number of these frames per hive, or, in other words, the proper size of a hive. I believe, with very many of our most successful producers, that small brood chambers are best, consequently I disor what hive to use. This has been the

They have objections that though theory may overlook, practice discovers at once. They are too thick and clumsy for summer, and too thin and cold for

winter.

Now, in regard to the surplus story of the hive, let us consider that under the head of

#### SECTIONS.

How to adjust them to the hive, what size and shape to use, and how many per hive, are the important questions. The method of adjusting that will give In the method of adjusting that will give us the chances frame and cleanest honey, with the least labor, is my choice always. There are many good methods used, and thought the rery best by numerous advocates, so I will pass on without further comment.

without further comment.

The size of the section is a matter of considerable importance. If it was not such a sin and sign of weakness to acknowledge a mistake. I would say that I believe the I lb. section is going to force its way to the front. All honor to

than 54/x64, because I prefer glassing entirely on the outside of the frame or section, believing, as I do, that this is the coming method. Of course, we must not be forced to buy fractional sizes of glass, that being poor economy. I put it on the outside, because we can glass nearly every comb where no separators are used in storing, and these separators cost me too great a portion of my surplus crop, to say nothing of their first cost and trouble of manipulating. I cannot be too enthusiastic in urging the use of handsome sections, and cases put on the market in the brightest and cleanest shape possible. Dovetailing is now done for just about the cost of nails to nail "prize boxes," and there is more than a dollar's difference in the labor of making up, in favor of the dovetailed section. I object to the all-in-one-piece section, and do not use them because of that naughty little sharp corner, that is always catching and causing the next section to leaf use them because of that naughty little sharp corner, that is always catching and causing the next section to leak, when raised up and pushed down into the case; also, because they are too liable to break, both at the time and after bending, and are not so true and solid as good dovetailed work. I find that by the use of proper methods of adjusting sections to the hive and proper care after so doing, there is no need of those nuisances called separators.

#### Bee House-Holy Queen, Etc.

MELVILLE HAYES.

I have twenty colonies in good condition, mostly in Langstroth hives. I fed 306 lbs. of best "A" sugar; use a cushion made of two thicknesses of coffee sacking with a layer of cotton between, nicely quilted, laid on top of frames; half inch strips to keep the cushion from coming down too close on top-bar leaving just room for bees to top-bar leaving just room for bees to pass over the top of frames. Have all my bees in a house constructed espe-cially for the purpose at a cost of about \$200. I may describe it to you some time. I know there is some prejudice against "bee-houses," but mine is a

against "bee-houses," but mine is a success.

I have two imported queens and one Holy queen. This queen I obtained from Mr. Jones at the National Convention. I doubled two reasonably strong colonies, deprived them of their queens for 24 hours; then caged my royal lady; placed her on top bars for 8 hours; and sprinkled bees and cage thoroughly with syrup, scented with peppermint, and then after the bees had become quiet, say half hour, opened the hive very quietly and let her go—it was a success. Two weeks later I let a friend have the queens out of two other hives and doubled the bees in with my "Holy" queen, following the approved methods, together with some of my own notions that never have been approved, but "all 's well that ends well." Today I opened the hive and found brood in all stages from the egg up, in six frames. She can out lay anything I in all stages from the egg up, in six frames. She can out lay anything I ever saw, and her bees are remarkably quiet and perfect beauties.

There has been fearful mortality among bees in this county. Here is a partial list. J. B lost 17 out of 20; N. S. lost 20 out of 27; G. E. S. lost 5 out of 8. These are the worst I have heard

The Editor of the American Bee Journal.

more secure against the bee-moth larva, but the convenience of moving and the solidity of the hive are important features in its favor. If our bees come out strong in the spring, they can clean out their dead and do it much cheaper than we can; if they are weak, the frames should come out any way and their brood, honey and general strength be looked to

always kept painted. All these woods are good enough, and I do not hesitate to use any and all of them; the difference is so small I do not consider it, as I always keep everything well painted.

PAINT.

I had supposed that white lead was the best paint, but such is not the case. The cheaper mineral paint out-wears it nearly two to one. So do the prepared paints in pails, though they are not the control of the propagation of the prepared paints in pails, though they are not the control of the propagation of the prepared paints in pails, though they are not the control of the propagation of the propagation of the prepared paints in pails, though they are not the control of the propagation of the propagation

carded two of the frames of my old standard Langstroth, and use an eightframe hive exclusively.

The porch I found not only extralabor and material, but too much of a spider's home, or saloon for idle bees. I have also discarded that. I prefer a tight bottom-board, nailed, and hermetically sealed by the bees. It is not only much more secure against the bee-moth larva, but the convenience of moving and the solidity of the hive are important features in its favor. If our bees come.

The judgment of Mr. A. I. Root in this regard. Mr. W. M. Hoge says to us from England: "It is with the greatest imaginable reluctance that I announce my despair of there ever being a satisfactory traffic in 'prize' or the section honey. If they could be distributed everywhere, with the combs safe and sound, they would be the most salable article ever introduced to the grocery traffic in 'prize' or the section honey. If they could be distributed everywhere, with the combs safe and sound, they would be the most salable article ever introduced to the grocery traffic in 'prize' or the section honey. If they could be distributed everywhere, with the combs safe and sound, they would be the most salable article ever introduced to the grocery traffic in 'prize' or the section honey. If they could be distributed everywhere, with the combs safe and sound, they would be the most salable article ever introduced to the grocery traffic in 'prize' or the section honey. If they could be distributed everywhere, with the combs safe and sound, they would be the most salable article ever introduced to the grocery traffic in 'prize' or the section honey. If they could be distributed everywhere, with the combs safe and sound, they would be the most salable article ever introduced to the grocery traffic in 'prize' or the section honey. If they could be distributed everywhere, with the combs salable article ever introduced to the grocery traffic in 'prize' or the section honey. If they could be distributed everywhere, with the combs salable article everywher

in a perfect atmosphere of complaints."

Now I feel that honey stored upon full sheets of properly made foundation, in 4½x4½x2 inch (1 lb.) sections, will go to England, and then all over the British Isles, if handled with any kind of skill and care. I speak from a few years' of experience with just such an article, and I feel that they settle the problem. They will "knock the bottom out" of the foreign traffic in comb and liquid in glass jars, just as the "prize" and larger sections and boxes "played them out" here. I pack these little solid fellows in glassed cases of 12 sections only, never glassing the honey.

I use 5x6 sections of 2 lbs. each in my

1 use 5x6 sections of 2 lbs. each in my out apiary, and I glass a part of the of 8. of, but from all 1 can learn 1 think at least one-half of the bees in this county are now dead. What is the cause? I do not know, who does? Wilmington, O., Jan. 2, 1881.

For the American Bee Journal.

#### Covering Bees with Snow.

G. M. DOOLITTLE.

The question is frequently asked, "Shall I cover my bees with snow?" and the answer is invariably given, "Yes, the more snow the better." Our experience has been that if snow is banked two-thirds the way up the broad chamber, it is a great advantage; but if the hives are covered two-thirds the way up the broad in the hives are covered two-thirds the way no the cap, or completely over, it is way up the cap, or completely over. It is a positive damage to the bees, and worse than no snow at all. Up to the winter of 1872-3 we had always wintered in the cellar, and not being as success-ful the previous winter as we desired, we concluded to winter on the summer we concluded to winter on the summer stands, and, as the snow fell, sweep it up around them. We did so, and by December 10 our hives were covered from sight, while the pyramids of white snow all over the yard made a very picturesque view which was quite enchanting. snow an over the control of the cont day was fine, they had a cleansing fight and all appeared well. We had little or no snow the rest of the winter, and when the season fairly opened we found that we had 29 colonies left out of 52. This loss we laid to the severe cold during April and the fore part of May, and believed that if we could have had snow to cover them all winter no loss would have presented. One thing we noticed. have occurred. One thing we noticed, however: all the hives we opened at the time of the thaw had brood in from the time of the thaw had brood in from two to four combs, while in April scarce a bit of brood was to be found in any hive. Of course we reasoned that had the snow continued, brood-rearing would have been kept up, and in the spring our hives would have been teeming with thousands of young bees, instead of depopulated colonies, as we then had. The next winter put an end to those visions however, for this time we had snow to keep them covered from we had snow to keep them covered from Nov. 20 to April 10. During the fore-part of February there came a warm day so our bees flew finely, and upon examination we found several hives that had brood in five frames to the amount of 50 square inches to the frame, or 250 square inches in all; while others that square inches in all; while others that were not buried so deeply, did not have over from 20 to 50 square inches. We noticed that the bees in those hives which had the most brood were so heavily loaded with feces that they were scarcely able to fly, while those with but little brood spotted the snow but little in comparison with the others.

However, we figured the 250 square inches of brood at 50 bees to the inch, and looked very wise when we told our

However, we figured the 250 square inches of brood at 50 bees to the inch, and looked very wise when we told our neighbors that such a colony would hatch out 12,500 bees in 21 days, and that we expected a rousing colony by spring. Cold weather with more snow came and held so till the middle of March, when we again had a day the bees could fly. Our bees were all shoveled out, and we expected to see plenty of those 12,500 young bees on the wing; but upon going to the hives our spirits were heavy to find all the old bees dead on the bottomboard, and those young, downy bees clustered closely together near where they had hatched, in the embrace of death. Not only this, but the old bees had consumed nearly all the honey in rearing these bees, so we had nearly a total loss, except the combs. When the working season arrived, we found we were again reduced to the number of 25 to star the season with.

warmth of the ground combined with the warmth of the bees, makes it so warm that the bees become uneasy, go to breeding, consume large quantities to breeding, consume large quantities of honey, thus distending their bodies and using up their vitality, causing them to die of old age during February, March and April, while the young bees have not the usual strength and vitality of bees hatched in September and October to withstand the rigors of winter, and thus comes spring-dwindling.

Two years ago, it will be remembered.

thus comes spring-dwindling.

Two years ago, it will be remembered, we wrote that the snow was 11 feet deep over a part of our bees. We tried as far as possible to keep the front side of all we could, shoveled clear; but we completely lost track of about 10 of them, and of the 10 not one was living the 1st of May. This in short has been our experience with bees buried in snow. With chaff hives the results are not so bad, still we would rather have none at bad, still we would rather have none at all than to have these covered 2 feet deep with snow.

Borodino, N. Y., Jan. 18, 1881.

For the American Bee Journal.

#### Successful Apiculture.

DR. S. STEVENSON.

If one should form his judgment of apiculture from some of the articles which he finds in the newspapers, he could hardly resist the conviction that to invest in hee-keeping, would, without a shadow of doubt, he to secure financial success. Practical, cautions and skillful apiarists in all countries know the case to be very different. There are certain fundamental principles which must be carefully heeded, if the apiarist would be successful.

First, the bee-keeper must be adapted to the business or else he need not ex-

to the business or else he need not expect to succeed, if he does he will be dissappointed. He must not only he adapted to the business (that is, made out of the right kind of stuff), but he subject patiently. must study the subject patiently, thoroughly and persistently.

This business requires constant study. No person should expect to succeed in the management of bees if he is unwill-ing to attend to them. They will suffer ing to attend to them. They will suffer from neglect just as promptly as domestrom neglect just as promptly as domestic animals or crops of growing grain on the farm. The man who will purchase a number of colonies of bees, set them up in some out-of-the-way place and give the matter no further attention should know out of the lawscow. tion, should keep out of the business

tion, should keep out of the business altogether.

Second, without an accurate knowledge of what should be the condition of a prosperous colony of bees at different seasons of the year, the keeper will be unable many times to decide positively whether anything is going wrong or not. The bee-keeper who is not fully resolved to get well acquainted with his little workers and to know as far as possible their nature, habits and peculiarities; neglects his best interests. Bees require prompt and scientific atpeculiarities; neglects his best interests. Bees require prompt and scientific attention, and if the apiarist is unable or unwilling to render it, his enterprise will be an unprofitable one.

Mr. C. B. Smith, of Leslie, stated in the Convention last year at Jackson, that he thought bee-keeping no more concertain than raising wheat or stock:

that he thought bee-keeping no more uncertain than raising wheat or stock; so I think. A farmer who is ignorant of the composition and properties of the soil he is trying to cultivate, of the different kinds of grain he raises, and who has no very definite notions of the distinguishing properties of the different manures in use, and, last but not least, who executes his farm work in a careless and slovenly manner—his success will be no better than the average careless and stoventy manner—ins success will be no better than the average bee-keeper. In the language of another, the success of a farmer depends on his understanding and complying with the principles on which God bestows a harvest." Just so with apientlure; if we much has engressful we must get acwould be successful we must get ac-

would be succession we make given a quainted with first principles.

We want to get rid, as soon as possible, of all notions about "luck," Every effect has its specific cause, and it is our business, and to our interest to search it out. We must make all our arrangements and business. total loss, except the combs. When the working season arrived, we found we were again reduced to the number of 29 to star the season with.

The difficulty seems that as soon as the hives are covered with snow, the life in the hives are covered with snow, the life in the hives are covered with snow, the life in the hives are covered with snow, the life in the hives are covered with snow, the life in the life in

See to it that all colonies are strong in numbers and in all respects in good condition. This cannot be effected without intelligent and unremitting attention. This suggestion of Mr. Doo-little was brought foreibly to my mind. one day last summer, by the remarks of a young man (son of a bee-keeper in my vicinity) who was examining my apiary. He said that "dad was going apiary. He said that "dad was going to put boxes on his hives as soon as he could get round to it." It was about July 12th then. The basswood honey had almost entirely disappeared; the white clover had produced nothing worth speaking of, and the result was that his honey crop was almost a failure. We must remember that a peculiar we must remember that a peculiar combination of circumstances and con-ditions conspire to produce a good flow of honey, and if we wish to profit by it, we must be up, dressed and ready for

Lastly, we must make every effort to secure our product in a neat presentable and inviting shape. If this last point is carefully attended to we shall have but little trouble in securing a sale for our product.

Honey has now taken its place as one of the staple articles of consumption. The fluctuations in price are no greater than that of other articles of food.

Morenci, Mich., Dec. 3, 1880.

For the American Bee Journal.

#### A Good Shade for Bee Hives.

L. JAMES.

As many persons have not the advantage of shade trees to protect their hives from the hot sun in June and July, I will describe, for their benefit, a plan I have tried during the last two seasons

with satisfactory results.

The ground was made level and freed of grass and weeds, and the hives placed in rows about 8 feet apart. Between these rows a narrow strip, not over a spade in width, was turned over over a spade in width, was turned over and in them sunflower seeds were planted early in the season (as the young plants will stand considerable freezing). As they increase in size they were gradually thinned out to 3 or 4 feet apart always leaving the thriftiest. And the under leaves and branches on these were pruned off to make it con-venient to get around among the hives. venient to get around among the faves. The ground was kept clean of grass and weeds by scraping them off with the hoe. In our soil, here in central Illinois, the plants grow from 8 to 12 feet high with large substantial stalks. A person who has never used them for this purpose will be surprised at the heautiful sight it presents in June and this purpose will be surprised at the beautiful sight it presents in June and July, giving ample shade, and furnishing good clustering places for the swarms, easy of access in hiding. The numerous large flowers furnish pollen in abundance, and some honey, and the seeds are good rich food for poultry.

Atlanta III

Atlanta, Ill.

For the American Bee Journal.

# Bee-Keeping in Northern Indiana.

JOHN CRAYCRAFT.

There are very few persons that keep their bees in a scientific manner, or with that care and attention that will bring that care and attention that will offing them success, hence it is only chance-work with many of them. There are a variety of movable-frame hives used here, and many box hives are still in use, which are about as good as any for those that scarcely ever open and look into their hives, and so little care is taken of them that they know compara-

taken of them that they know comparatively nothing of their condition.

I have made inquiry of a number of persons having bees, and nearly all report their bees as dying or dead. The past was a very poor year for honey, and the poplar (tulip tree) bloom, the first and second weeks in May. Many divided their heast their in anticipation of a good their bees then, in anticipation of a good season, and now their bees are about all gone, through their neglect to feed them gone, through their neglect to feed them sufficient at the proper time to keep them until spring, thinking they could feed them any time with safety. I find it is almost certain death to the bees to attempt to feed them in cold weather, more especially in such a winter as this

has been thus far. They have been contined to their hives since the 1st of they will be in another month, during which time most of them will die for

want of food.

I have my bees all in double-wall (Langstroth frame) chaff hives, reduced to about 6 frames, cushioned on each side, and the hives filled on top with dry sine, and the nives med on top with my planing-mill shavings, set on sawdust, and banked around with the same as high as the brood chambers. They are put away with sufficient stores to supply them, until the 1st of March, but the quality is not as good as I would have liked, being mixed too much with the jnices of peaches and apples Salem, Ind., Dec. 29, 1881.

For the American Bee Journal.

## How my Bees are Wintering.

H. R. BOARDMAN.

I have perused the third number of the Weekly BEE JOURNAL. I think I am justified in saying that it is an im-portant move in the interest of bee-culture. I will acknowledge that I felt somewhat disappointed and indignant when I received the first number, for I was very much introduced to the ald was very much attached to the old American Bee Jounnal out of which A MERICAN DEE JOUNNAL out of which I had learned so many good things, and it seemed almost like bidding good-bye to an old friend. But I am more than compensated for

the disappointment in being able to hear the disappointment in being able to near from my bee-keeping friends all over the country each week, and all about how their bees are wintering during these long cold winter spells. It is like these long cold winter spells. It is a continual feast to be in weekly munication with our brother bee-keep-

munication with our brother bee-keepers. And here I am reminded that perhaps others might take the same pleasure in reading my report.

1 am wintering something over 200 colonies in two bee-houses, about one mile apart; the one at home has 140 colonies in two rooms, 10x19 feet each. colonies in two rooms, 10x19 feet each. The temperature has averaged a little less than 40 above zero. Many of the colonies were light; they were put in just about the middle of November before the cold weather set in. I visit the bee-rooms each day and make a record bee-rooms each day and make a record of the temperature, condition of the hees, &c. I raise the temperature a few degrees once in a week or 10 days, if very cold, by means of artificial heat. My bees have been very quiet up to date and are in perfect condition.

date and are in perfect condition.

I feel much confidence in my ability to solve the wintering problem and make the wintering of bees successful, attended with no more risk than the wintering of other stock.

East Townsend, O., Jan. 26, 1881.

For the American Bee Journal. The Season and Wintering.

JOHN F. COWAN.

The spring and early part of summer The spring and early part of summer were unfavorable for bees in this part of the county; there was an abundance of fruit blossom (I think that I never saw the equal before); considerable white clover blossomed, but neither seemed to yield any honey. Our bees were in a starving condition from spring till the middle of July. Soon after which the smart weed began to bloom, and the bees commenced breeding and and the bees commenced breeding and

which the smart weed began to bloom, and the bees commenced breeding and gathering honey very rapidly.

We had 28 weak colonies of bees to begin the season with, from which we obtained 500 lbs. of nice extracted honey and increased to 62 fair colonies.

We have our bees well packed for winter in chaff-hives, with plenty of stores. I believe that chaff-hives on the summer stands is the best and most convenient method of wintering, and bee keepers are drifting into that method of wintering.

I am following farming as a business now, but expect to make bee-keeping a specialty in a few years. I am a subscriber to the Journal and do not think that any bee keeper should do without it, as it treats on every subject which is of interest to bee-keepers generally. So long life to the Weekly Bee Journal.

Wellington, Ill.

Tenement Hives for Wintering .- My bees are in good condition so far. I have 35 colonies in the cellar; they are all very quiet. I have 25 colonies packed in chaff that are wintering very nicely. I have 3 in chaff tenement hives, that I think are doing the best. I have win-tered for two seasons in the latter, and tered for two seasons in the latter, and like them very much. They seem to be proof against spring dwindling and swarming out. Is there such a patent hive as "Torrey's"? He says he had it patented 10 years ago. I thought that there were but a few patent bee-hives now, Allhailthe Weckly Bee-Journal. Athens, Maine. WM. H. Green.

(Probably Mr. Torry has a patent on his bee-hive; no, indeed, their name is "legion." They are almost innumerable—and the patented features are usually the most useless or objectionable.—Ed.]

Winter in Texas. - We have had the most winter—most cold—that I have ever seen in Texas, and it harts worse ever seen in Texas, and it harts worse here than in your country—the sudden changes—here, one day bees will be flying nicely, sun shining brightly. Elm buds begin to smell and the people begin to think of putting their ground in order for another crop when suddenly, in 20 minutes, it will be freezing cold. The thermometer only a few days ago gan from 10 to 20 to inside of 20 minutes. The thermometer only a 1ew (also ago ran from 60- to 30- f. inside of 30 minntes, a cold northwest wind, called "Northerners" or "Northers." We have had more sudden changes this winter and last fall than ever known to the oldest inhabitants or for the last 35 years. I wish the new departure, giving us a weekly American Bee Journal, all the success that its editor could anticipate. We half it with joy.

Wm. R. Howard Kingston, Texas.

Satisfied.—I am certainly under many obligations to Prof. Cook for the good report he gave in the BEE JOURNAL of the queen I sent him. I have not another word to say about it.

D. A. Pike. Smithsburg, Md., Jan. 24, 1881.

Bees Uneasy.—My bees are getting uneasy and begin to show signs of dysentery, and unless there comes a warm spell soon, many will be lost. They spell soon, many will be lost. They come'out at all times of the day and fly off, never to return. Why they do so, I am unable to find out. The hives are dry and clean, well packed in chaff as Prof. Cook directs in his Mannal. They have plenty of honey and pollen and the reason may be that there is too much pollen. I have 6 tenement chaff-hives, with 4 colonies in each, and II of Root's single chaff-hives, also, a lot of Simplicity and Langstroth hives packed by Cook's method. Thus far the tenement hives keep bees in the best order. The combs run parallel to the entrance.

B. F. Pratt. B. F. PRATT.

Dixon. Ill., Dec. 28, 1880.

Alsike Clover.—I think the article on asike clover, in the first number of the Weekly Bee Journal, will be a great help to get the farmers about here to sow it, for red clover kills out here in an open winter. I think the alsike will do better. A neighborhas a few acres and he says he was not troubled with it heaving out in frosty weather; he says it makes the best of hay. I have long been anxious to try it, but have no place I have long been anxious to try it, but have no place where I can give it a fair trial, and so far, have not been able to get any one else to try it. I go into winter quarters with 89 colonies, mostly black bees, in good condition for winter, in chaffpacked hives. Our season here for 1880 has been the poorest for 5 years. I obtained about 4,500 lbs. of comb honey from 80 colonies in the spring, and increased to what I now have, besides I have done some work for next year; so I have no reason to complain.

For Brood,—1 have lost 100 colonies during the past 2 years by that terrible scourge—foul-brood.—1 have about a dozen colonies left in my cellar in good condition, and think I have mastered the disease now. If I can fill up my the disease now. If I can fill up my apiary in the spring, I intend to regain what I have lost.

WM. DYER.

Hastings, Minn.

Much Loss Expected.—Bees that were not sheltered during our recent cold weather will perish, and colonies will be scarce here next spring. I have 25 colonies in the celler, covered with wool colonies in the cener, covered with wool cushions, and 2 buried in the ground. All seem quiet. I wish you much success with the Weekly BEE JOURNAL.

Waterloo, Wis. E. BUMP.

Northern Michigan for Bees.—There are many peculiarities about this part are many peculiarities about this part of Michigan, and it was thought until quite recently that bee-culture could never be a success in our country; but one enthusiastic bee-keeper, with the aid of your most valuable Journal, has established the success. The gentleman to whom I refer is Mr. G. O. Grist, of Northport, who has a fine apary in a flourishing condition. I have about 30 colonies, which are of his stock, and are wintering well. Our stock, and are wintering well. Our honey crop last season was light, owing noney crop last season was light, owing to dry weather. The wild asters, gold-en-rods and white clover, are our best honey plants, although we have many others. I wish you success with the Weekly Bee Journal. Omena, Mich. J. P. Greene.

Likes Chaff-packing Best.—I have in winter-quarters 53 colonies; 46 in chaff on summer stands and 7 in cellar. My experience so far is in favor of chaff packing, especially in an open winter. The season has been poor in this vicinity both for increase and honey. I have the black, Italian and hybrid bees, but desire another season to stock my apiary with either Italians or Cyprians. I desire your candid opinion which would be best. I cannot do without the BEE C. S. INGALS. Morenici, Mich.

[The Cyprians as yet are not sufficiently tested to give an opinion. The Italians when bred to their best qualities are good-and may or may not be eclipsed by the Cyprians.—ED.1

Poor Results.—Last season I commenced with 16 weak colonies which dwindled down to almost nothing, so that it took all the spring to build them was fair colonies. up to fair colonies. I increased to 2 and obtained about 750 lbs, of honey, The season was too dry the nights, were too cold, and there seemed to be no nectar in the bloom. Success to the Weekly BEE JOURNAL.
Sing Sing, N. Y. HIRAM RICHEY.

Italian vs. Black Bees.—A weekly journal is what we all need and especially those of us who are young in the business. I have been handling bees three years: I have not done a large business but have made it pay. I have now II colonies all snugly packed with buckwheat chaff, taking their winter nap. Five colonies are Italians, which outstrip the natives in obtaining honey, until buckwheat bloom, of which we generally have abundance: then our black fellows bring in the most honey, Nothwithstanding this I much prefer the yellow or Italians, for reasons I shall not now give.

Last season was not a good one here for honey, 52 lbs. was the largest amount Italian vs. Black Bees .- A weekly

Last season was not a good one nere-for honey, 52 lbs, was the largest amount 1 obtained from any one colony. This was comb honey. I have sold nearly all my crop here at 18 to 20 cents per 4½x4½ section. I wish the Weekly much success. J. W. CARTER.

Four Months' Confinement.—Bees in this section have not had a single flight since the last days of October, now nearly 3 months and they are liable in this climate here to be kept in-doors for 2 months longer. Hope the result will not be disastrous, but am a little afraid.

O. O. POPPLETON.

Williamstown Lowa Jan 25 1881. Four Months' Continement. afraid. O. O. Poppleton Williamstown, Iowa. Jan. 25, 1881.

Not very Encouraging.—I have been a constant reader of the American Bee Jouanal for several years past and do not think 1 could well do without it. However, I want to suggest a little improvement that would add much to the provement that would add much to the convenience of reading and handling, that is to have the edges cut and paste the backs like the Standard and Farmers' Review of Chicago. I had one swarm last year from 22 colonies, and 20 lbs. of surplus; not very encouraging, but I want to try again. I have my bees in the cellar where it is total darkness and I shall leave them there until April; the entrances are open which keeps them as quiet as so many thes. I have wintered them in this same cellar for years, without loss. I hope that we nave wintered them in this same cenar for years, without loss. I hope that we may have a good season in 1881, and that the JOURNAL will meet with much success in its "new departure." J. M. A. MILLER. Galva, Ill., Dec. 31, 1880.

Not Discouraged.—I did not realize anything from my bees last year and they only have honey enough to keep them this winter. I am not discouraged however, but hope for better things another season. My best wishes for the another season. My best wishes for the prosperity of the Weekly BEE JOURNAL. 1 know it will be good, in any torm, as long as we have the present editor and proprietor.

J. A. AUSTIN. Huntsville, Ala.

Good Enough.—I have made \$25.00 profit, per colony, this season, rearing dollar queens for sale. Perhaps some would like to know how it was some Would like to know how it was done. If any of the breeders who rear high-priced queens only, have made more than this per colony, this season, let us hear from them.

W. Z. HUTCHINSON.

Rogersville, Mich.

What ails my Bees !—Last spring I formed a nucleus, by taking 3 frames ont of an old hive with which to start it. They did well, filling all the frames (Langstroth) and are nearly all full at present. But for the last two or three weeks they are dying at a fearful rate. the thermometer at 50° above zero) and I ind hundreds of them dead—sticking to the comb. I find also near one corner of the hive some combs that are mildewed. This is on the combs I had taken from a hive in which the bees had please give it. My bees that are not troubled as aforesaid, are flying as though they meant business for the balinf the winter.

II. B. MAY. died. Is there any remedy? If so, please give it. My bees that are not ance of the winter. H. B. Oregon City, Ore, Jan. 3, 1881.

[The bees sticking to the combs became separated from the cluster, for some cause, and chilled. Had they died from age or disease, they would mostly be on the bottom-board. The mildewed combs better be given one each to your stronger colonies.—Ed.]

Opinions concerning the Journal.

I like the change from a Monthly to a Weekly paper, made by you, of the American Bee Journal. Will you allow me to give a suggestion, it is this, run the paper through a sewing machine to bind it, it will not take long, about 500 could be run through in an hour

I have received the Weekly Bee Journal. I think it looks splendid. It is the "boss" bee paper. Success to it and its editor. EDWARD B. BEEBEE.

1 would like to add my feeble voice in praise of the Weekly Bee Journal. No bee-keeper that is alive to the business would do without it.

ALBERT E. FOSTER.

I am much pleased with the Weekly Bee Journal and trust it will prove as profitable to its publisher as I am sure it will be to the progressive bee-keeper. E. T. Flanagan.

I wish you every success with your Weekly enterprise and hope that you and I will live to see a "daily."

G. STURGEON.

I can never express how much I value the Bee Journal. I am proud to say that this is the third year I have taken it. Each number I value most highly -number me among your subscribers, St. John T. Moore.

I have received the three first numbers of the Weekly Bee Journal. I like it very much, in fact I do not see how a man can be successful in keeping bees without it. Best of all is we can have DAVID ARTER. it weekly.

#### Convention Notices.

We have accepted an invitation to attend the Ashtabula County, O., Convention, which is to be held at Andover, O., on Tuesday and Wednesday, Feb. 8 and 9, 1881. On the evening of Tuesday, the 8th, we have engaged to deliver a public lecture on "Bees and Honey." There being a large number of beekeepers in that region, we expect the meeting will be very largely attended. All interested will please notice the date—as it has been changed. as it has been changed.

The annual meeting of the Southern Michigan Bee-Keepers' Association will be held in Battle Creek, Mich., on Wednesday, Feb. 9, 1881, at 10 o'clock a. m. B. Salisbury, Sec.

The Nebraska Bee-Keepers' Association will hold their Annual Convention, on the 10th and 11th of February, 1881, at Plattsmouth, Cass Co., Neb. Western Iowa bee-keepers are cordially invited to attend invited to attend.

HIRAM CRAIG, Pres.

The Rock River Valley Bee-Keepers' Association will hold their annual meeting at Monroe, Ogle county, Ill., on Feb. 8, 1881. The weather was such that our Secretary was not at our last meeting and our Secretary pro tem hav-ing failed to send in his report, I send A. RICE, Pres. the above notice.

The Marshall County, Iowa, Bee-Keepers' Association will meet at the Court House in Marshalltown, Iowa, on Saturday, Feb. 5, 1881, at 1 p.m. Subject for discussion: "Winter care of bees."

J. W. Sanders, Sec.

A Bee-Keepers' meeting will be held at Walnut Hill, Barren Co., Ky. on Saturday, Feb. 12, 1881. All are invited.

II. C. DAVIS, Sec.

The Northeastern Bee-keepers' Association will hold their Eleventh Annual Convention, in the Common Council chamber, at Utica, N. Y., on the 2d, Committee and the Council Cou

mentioned, one tested Cyprian queen, donated by L. C. Root.

Diplomas will be awarded for best display of implements; the best comb foundation for brood-chamber; for surplus boxes; best honey extractor; best be smoker; for the most practical bee hive.

One dollar each, for the best crate of honey in the most marketable shape, and for the best package of extracted honey.

For the inentes and best honey crate and section hoxes cost, quality and finish to be considered), one tested Italian queen, donated by Ges. W. House.

All are invited to send implements for competition or exhibition. Articles sent to the Secretary will be sold or otherwise disposed of as the owner may direct. It is desired that all articles sent be the same as kept in stock, or forwarded to purchaser.

GEO. W. HOUSE, Sec. L. C. ROOT, Pres.

For the honor of the fraternity in New York, we hope that the friends of truth and justice will be present at the above meeting. The very unjust resolutions, passed a year ago, should be rescinded and thus in a measure blot out the disgrace which now attaches to the last North Eastern Convention. Many were indignant at the matter then, and we hope they will make an effort to be there, to assist in "making the crooked things straight." We do not imagine that it will be difficult, for some of those who were interested in passing them, if we mistake not, will now labor to have them reversed .- ED.]

I have no reason to complain.

G. W. STANLEY.

Wyoming, N. Y.

#### THOMAS C. NEWMAN,

EDITOR AND PROPRIETOR.

CHICAGO, ILL., FEB. 2, 1881.

This Number of the BEE JOUR-NAL, being the first issue of the Month, goes to all our subscribers-the Monthly and Semi-Monthly, as well as the Weekly.

The Michigan Farmer, a firstclass agricultural paper published at Detroit, Mich., says: "The AMERICAN BEE JOURNAL is now published weekly, and is very acceptable in its new form.

Mr. W. J. Davis, of Youngsville, Pa., like all bee-keepers, is an enthusiast. The Warren, Pa., Mail of Jan. 18. gives him the following notice: "Our friend, W. J. Davis, Esq., of Youngsville, was up the other day and made us a pleasant call. It is always pleasant, as well as instructive, to hear him talk about honey bees. His apiary, for quality at least, is probably the best in the United States. He keeps the Italian bees, which are considered something extra. He says he is about out of bees

the employ of Messrs. W. Harrison & L Son, of London. England, having severed his connection with Messrs. Thurber & Co., of New York. Respectletter says: "I certainly think you deserve the warmest commendation for Weekly, and I trust that the bee-keepto it a hearty support."

Please remember that if you forconvenient to refer to a copy of the JOURNAL for it-it is no use to address "Tom Newman, Chicago," Two letters addressed like that have been sent to the Dead Letter Office in Washington and returned to the writers—and are now on our desk, after a month's delay. If you forget everything else and want a letter to reach us, and address it "BEE JOURNAL, Chicago"that will find us, sure; for though there are many Newmans, there is but one BEE JOURNAL, and the postal clerks, are well acquainted with it.

OUR PORTRAIT.-The following letter is one of many similar ones:

"Holland, Mich., Dec. 15, 1880.
Mr. Thomas G. Newman: Dear Sir—Will you please give to your readers in the first Weekly Bree Journal, an engraving of your likeness. Many of us, who have never seen you, would like to see it.

MARTIN PELON."

We could not give it in the first number, as there was not time enough to we shall add that improvement to the get it engraved and ready, so we concluded to leave it for the first number in February, and to-day it may be found in the first page. Those who have seen it, say it is a good likeness.

#### Naughty Lizzie Cotton.

We are sorry to see that the Farmers' Review of this city is publishing the advestisement of that fraud-Lizzie Cotton. The Kansus Farmer has been solicited to do the same, but declines, and publishes the following:

Indishes the following:

Lizzie E. Cotting!—Ah, Lizzie! you eruel siren, you wish to advertise your remarkable "New System" of beekeeping in the Farmer. Well, Lizzie, you can't do it. The bee folks say you are a fraud. In fact, Lizzie, they go so far as to say you are a confidence man. We advise all young bee-keepers to stop their area of the theorems of the theorems. We advise an young nee-keepers to stop their ears or tie themselves to the mast while passing the *hire* on which you sing, like the old mariners when passing the fatal island where the famous three of mythology sang.

She advertises a hive, that is a useless trap, when sent; but usually she returns nothing for the money sent. Her book" exists only in advertisements or imagination. Mr. A. I. Root sent her a dollar for the same book years ago, and has her letter of acknowledgement, and later ones promising the book as soon as published, yet the book fails to appear.

Mrs. L. Harrison, in the Prairie Farmer, makes the following remarks concerning her [or him.]

"In Mrs. Cotton's circular, she says that by using her hive two hundred pounds of honey can be obtained, in localities where forty pounds by other methods, is considered a large yield. A wonderful hive surely; we always thought that bees gathered the honey. but it would anywer from Mrs. Cotton's

extra. He says he is about out of bees—having now only 116 hives! He sometimes keeps over 250."

There is another wonderful apiary (on paper) located in Missouri which we would caution our readers against sending money to. This swindler is known by the name of N. C. Mitchell."

😰 Prof. A. S. Knapp, of the Iowa Agricultural College, makes the following mention of the BEE JOURNAL in ing the BEE JOURNAL Mr. Hoge in a the Gate City, Keokuk, Iowa: "The AMERICAN BEE JOURNAL is the oldest bee paper in America, established in bringing out the Bee Journal as a 1861, in Chicago, by Thomas G. Newman, and has been conducted with ers throughout the country will extend marked ability and success. It is cosmopolitan: it covers the practical and scientific, the home and foreign. Whoever reads it will be well informed upon get our name and address, and it is not the history, progress and practice of bee-keeping.

> ₩e were agreeably surprised with a New Year's call from Mr. F. F. Collins, Vice President of the North American Bee-Keepers' Society for Texas. Mr. Collins' headquarters are now at Houston. He reports the past season to have been very satisfactory to beekeepers in his State, except in the vicinity of Dallas, where foul brood prevails to a considerable extent, he having lost all his again last season from that cause. Our bee-keeping friends visiting Texas will find Mr. Collins one of those largehearted, whole-souled gentlemen whom it is a pleasure to meet.

> We desire to cut and paste the leaves of the BEE JOURNAL, and should have introduced this feature a month ago, but it requires costly machinery to do it. But few are in the city, and these are constantly employed. More are being introduced, and as soon as possible, JOURNAL.

When changing a postoffice address, mention the old address as well as the new one.

#### Melilot Clover as a Honey Plant.

I find by the BEE JOURNAL that it is altogether in favor of melilot clover, as altogether in tayor of inclinic clover, as being the most profitable for bee pasturage. I desire to try it.

1. Where can I get the seed, and what will it cost?

2. How much is required to the acre, and when ought it to be sowed?

What kind of ground will be the best, and what amount is necessary for

4. After once seeded, will it seed itself?

5. Does it have to be seeded every 2 land. The Telegraph says:

I have about 60 colonies, and am using

"the winter hive." REV. A. MCKNIGHT. Bible Grove, Hls., Jan. 4, 1881.

#### ANSWERS.

1. We think you can obtain the seed from almost supply dealer; Mr. Alfred H. Newman, Chicago, keeps them in stock at 30c. per lb.

2. Five pounds per acre; during the first spring rain is as good a time as any. Scatter the seed thoroughly, then barrow it in lightly.

3. We have never seen any soil too good nor too poor for it; it will appreciate any waste spot donated to it. amount required depends upon the want to be supplied. If there is plenty of white clover and basswood, then two or three acres of melilot will supply honey for them to subsist on and keep up breeding nicely till fall bloom sets in. If there is neither white clover nor basswood, then more melilot is required, say, one acre for every live colonies—we cannot answer precisely, as we have no positive data. At the BEE JOURNAL apiary last season we kept an average of about 100 colonies, which had nothing but the melilot that grows spontaneously along the streets and a few waste places in our neighborhood, from which to gather stores. White clover yielded no honey, nor did basswood. We run but four colonies for honey, and obtained perhaps a hundred pounds of extracted from each. We cannot determine what the others might have done, as we were continually dividing them, testing or nursing queens; they were often queenless, and experiments were the rule rather than the exception. From some, perhaps all, we extracted a little, sometimes close, and at other times but a trifle, as the nature of an experiment required. But we put away our bees with sufficient honey to live on under ordinary circumstances. This was from the spontaneous growth of sweet clover, certainly not more than enough to cover ten acres, perhaps not much over five. The little honey obtained from the willow, elm and maple shade trees was consumed as rapidly as gathered, in early spring, in brood-rearing.

4. Yes; we think it will. If, however, the same ground be planted in early spring and again in the fall, it would insure a profuse annual bloom, and as it replants itself biennially, all trouble of cultivation is at an end.

### 5. Answered above.

all would be particular to give their P.O. address and name, when writing to this office. We have several letters (some inclosing money) that have no names to this office. name. Many others having no Postoffice, County or State. Also, if you live near one postoflice and get your mail at another, be sure to give the address we have on our list.

#### Flashy and Trashy Literature.

For the past two or three years there seems to have been a perfect mania for publishing books, circulars and magazines on bee-culture. Of course, those only that are valuable will survive, and the rest will soon be lost to memory. We were strikingly reminded of this upon reading the following "notice" given by the Daily Telegraph of a new pamphlet, published in London, Eng-

"British Bee-Farming; its Profits and Pleasures." By James J. Robinson, London: Chapman and Hall.—During the past three or four years various manuals of bee-keeping have appeared. The displays at the Crystal Palace and elsewhere of the operations of bee driving, &c., have called public attention to the pursuit, and those who wish to undertake bee-keeping scientifically to undertake bee-keeping scientifically have only to consult one of the various excellent manuals, or, better still, the very excellent monthly publication issued by the well-known bee-master, Mr. Abbott, of Hanwell. The subject there has been as the control of the subject there has been as the control of the subject there has been as the control of the subject there has been as the control of the subject there has been as the control of the subject there has been as the control of the subject there has been as the control of the subject there has been as the control of the subject there has been as the control of the subject there has been as the subject th Mr. Abbott, of Hanwell. The subject there has been so thoroughly ventilated that we expected that some advance at least would mark any new work upon the subject. Such is not the case with the book before us; indeed, so completely behind the age is it that after reading for a while we looked backed at the title-page to see whether it was not a new edition of some work published half a century since. It is somewhat carelessly and hastily written. One passage contradicts another; one instruction nullified one that has gone before; while the sanguine calculations of profits are calculated to do infinite harm profits are calculated to do infinite harm both to those who, on the strength of the profits held out, may embark upon the culture, and so by their failure and disappointment may hinder the spread of what is a really valuable addition to the laborer's cottage garden. We could multiply instances of the slovenly way in which the book is put together. An advanced apiarist will know what to think of it when he finds that in joining weak colonies no advice is given as to weak colonies no advice is given as to the previous capture of one of the queens, or the sprinkling both colonies with some slightly perfumed liquor, precautions taken by all who can pre-tend to be scientific bee-keepers nowadays. The deceptive nature of the statistics of the book may be judged by the fact that it is solemnly recorded that the annual product from each colony should be worth ten pounds—more in good seasons; but even in poor seaand good seasons; our even in poor seasons it should clear six. It need not be said that any one who takes up beckeeping with Mr. Robinson's book in hand, and with his head filled with Mr. Robinson's calculation as to the profits to be derived from each colony, is destined to a dismal and disastrous awakening to the facts of bee-keeping."

With "N. C. Mitchell," "Lizzie Cotton," and some others, who are publishing trashy and flashy literature with which to beguile the minitiated, we can sympathize with our British brethren. Care should be taken to follow the teachings of those only who are known to be successful apiarists. The work of Messrs, Geo. Neighbour & Son being a standard book for England, as Cook's Manual, Quinby's New Bee-Keeping and Root's A B C are the standard books of the present day for America.

Sample copies of the Weekly BEE JOURNAL will be sent free to any It would save us much trouble, if names that may be sent in. Any one intending to get up a club can have sample copies sent to the persons they desire to interview, by sending the

> Notices and advertisements intended for the Weekly BEE JOURNAL must reach this office by Saturday of the week previous.

#### Pure Liquid Honey in Glass Jars.

By express I send, carriage paid, sam-By express I send, carriage paid, samples of absolutely pure honey prepared without addition or adulteration, so that it will never candy. I have prepared honey in this way for the past eighteen months, putting it to the severest test and have yet to learn of a single ease where it fermented or congetted. I wish you would tree to conde those employed. you would try to eandy these samples if you can—expose them to the sun light, or put them in the coldest place you can -only keep the bottles corked, except when you are testing its purity.

To practical bee-keepers engaged in To practical bee-keepers engaged in marketing honey it is hardly necessary to say a word as to the importance of this discovery. The popular demand is for comb honey—and the only way for distributing comb honey sound and attractive, is to cut it up and pack it in glass jars. Heretofore a prejudice has existed against honey packed in this way, because so much glucose had to be used to keen it limpid but now, that used to keep it limpid, but now, that only pure honey will be used, these packages will fast become popular. 1 claim the following advantages:

- 1. Safe distribution of comb honey.
- As large quantities of extracted honey will be required to pack the comb, in this way, an outlet will thus be made for the extracted as well as the comb.
- 3. Where combs are cut up, frames can be used instead of section boxes.
- It will shut out glucose more effectual than legislation.
- Cut comb honey in flint-glass jars is the most beautiful way of putting it up. It suits the dealer, it pleases the consumer, because it is handsome, because the package will not leak, because the honey will not congeal, and because it can be guaranteed to be pure.

I have avoided saying much about this while testing it, but now I consider it a success.

W. M. Hoge.

New York, Jan. 17, 1881.

These samples came safely to hand, in a patent "pliable metal envelope," covered with paper outside—a really nice thing.

The samples of honey appear very nice and clear, but we have had no time to get them analyzed, to test their purity. They show no signs of granulation, however.

One of the most reliable tests for pure honey is its granulation—and consumers are being educated to suspect all that is not candied in the fall and winter months

The popular prejudice is rightfully directed against comb honey in glass jars-knowing that nearly all of such is surrounded with a vile compound of which glucose is the chief ingredientthis Mr. Hoge will have to overcome if he ever makes his plan successful, but we fear it will be a long and tedious undertaking.

Three years ago, we took some of our honey from melilot clover to a chemist and had it clarified. This we took to several Conventions in this country, and also to England, Scotland, Wales. France, Switzerland, Italy. Austria, Germany and Belgium, and exhibited it to the most noted apiarists in the World. It is now on our desk, and is as yet not candied. We expect Mr. H's plan is similar—and if so, of course the honey is pure. Ours was only subjected to the "water bath," and "percolated." We had intended to experiment further with this method, but a multitude of cares and duties, public and private, have prevented us from doing so. We are glad that Mr. Hoge has now taken thanks of honey-producers, for any efforts tending to putting a stop to the adulterations, now so much practiced.

most persistent and powerful depresser out not with you miger (unless for a furnished by his date of temperature. But since the structure cartoon). I used the line in a feeder tits the only one even the form of the circulation of insects is very a late. Van Densen, made flat and laid was in good health broadside next the bees under cushion; are glad to be able to for us here to note that its action is due this was troublesome, requiring free a satisfactory nature.

#### LONDON JOURNAL OF HORT.

Feeding Bees with Whisky, -Mr. Frank Cheshire is one of England's most scientific and practical apiarists, whom we had the pleasure of becoming acquainted with while in England in 1879. He makes the following comments upon an item which was given on page 13 of the BEE JOURNAL:

"Different kinds of sugar, such as sucrose, glucose, and lactose, agree in containing carbon, hydrogen, and oxygen, the latter two in the proportions in which they form water. This sugar becomes the heat-giver to the bee in the following manner:—Air containing oxygen is taken in by the bees through oxygen is taken in by the bees through spiracles' (the breaking openings) in the sides of which are fourteen in number, and this oxygen is by degrees united with the carbon of the sugar, which is being carried about in solution in the fluids of the insect. The carbon thus becomes a part of a gaseons product—carbon dioxide, which is thrown out from the breathing tubes (trachea) at every contraction of the abdomen. The union of oxygen and carbon is always attended with a great evolution of the at, and is, indeed, the sole cause of the fervor of a charcoal tire, and mainly the fervor of a charcoal fire, and mainly gives intensity to one of coal. Heat, then, is developed within the bee's body as this chemical union progresses, and during the winter each insect plays its part in keeping up the temperature of the cluster. It must be added to save misconception, that in certain circumstances the organized tissue of the insect may itself unite with oxygen and sect may itself unite with oxygen and contribute the heat formation, but our argument will be made the clearer if this point be left out of view.

"We have now to consider the physi-

ological effects of alcohol to ascertain whether the bee would be likely to be assisted by it in keeping out the cold, and here we must argue from its welland here we must argue from its well-ascertained action upon men and some of the higher animals; but in this we shall be justified, since morphia, strychnia, aconite, and some other drugs are well known to microscopists to influence creatures even so low in the scale as infusoria and rotifera after the same manner as they effect those with the most complex organization. Numberless experiments muon men, dogs, and most complex organization. Number-less experiments upon men, dogs, and pigeons have clearly shown that alchol inders the union of oxygen with carbon in the vital fluids, and in consequence a smaller amount of heat is produced during its presence in the blood, while it follows that less carbon dioxide is it follows that less carbon dioxide is thrown out. Applying this to the bee, it would follow as a matter of course that it would be far less able to withstand the rigors of winter with it than with-out it. Those who know anything of the history of our arctic expeditions will recognize the complete corroboration which these give of the truth of this werecognize the complete corroboration which these give of the truth of this position. That alcohol produces a feeling of flush is well known, but the cause is the partial paralysis of the pneumo-gastric nerve, the duty of which is to hold in check the minute blood vessels. The check removed the blood vessels strately check removed, the blood vessels stretch out under the pressure of the contained blood; and a general surface blush is the result; but this no more produces warmth than would turning the hot inside of a manure heap to the surface warm it. Indeed it is an act of cooling, warm it. Indeed it is in act of cooling, in which heat that before was deeply seated is made to display itself, but is at the same time lost by dissipation in the surrounding air. Those who care to surrounding air. Those who care to look to the *Lancet* for August 25th, 1866, will find details of some remarkable experiments tried in University College Hospital, putting this matter in the clearest light, and showing that alcohol immediately after the first flush is a most persistent and powerful depresser

to its lowering of nerve energy, than quent refilling. I will use, this winter, which nothing would be more likely to on my weak colonies, a box made like unfit bees for battling with the adverse your chaff-cushion division board, and conditions of a protracted winter. That alcohol may give a flash as it were none. Chloride of calcuim (calcined) will will deny; but even this it does not do absorb much more water than lime, and will deny; but even this it does not do because it gives strength, but because it renders a further paying-out of our resources possible; but as they are paid resources possible; but as they are paid out we are left poorer, weaker, than before, hence the excitement brings exhaustion, and the higher the one the deeper the other. Alcohol is an irritant, and therefore a waster of vital energy, and so the very reverse of that needed by wintering bees, every power of which should by all means be husbanded in order that returning spring may find them with a large balance of may find them with a large balance of energy still standing to their account. "Three powerful reasons, amongst se-yeral others unmentioned, are now be-

veral others unmentioned, are now be-fore us, each one by itself sufficient to condemn alcohol as a part of hee food. We find it hinders oxidation and pre-vents heat being developed. It lowers nerve tone, and so in the end weakens. It irritates and therefore exhausts, while, so far as I have been able to dis-cover, it does not bring us for these vils one countervailing advantage.
"Good indeed would it be for many

if the old unscientific delusion that alcohol keeps out the cold were altogether dispelled; but I write because I am deeply convinced that it will be good for our bees when every bee-keeper knows that protection keeps in the heat and that good honest sugar is the right thing to produce it."

#### GLEANINGS.

Lime for Wintering.-Mr. C. Lover. Reistertown, Md., remarks as follows:

"This will be a hard winter on bees in most parts of the country, on account of lack of good stores, and mostly old bees—a poor prospect certainly. We must help the little fellows, or make up our minds to lose them. Last winter 1 kept 10 colonies warm, dry, and in good health, by chemical means; i.e., by a generous use of quickline. My by a generous use of quicklime. My other colonies had the dysentery, and every one of the chaff hives were mildewed and wet, in spite of three dryings during the winter; while the 10 cushions used on the hives with lime, were as dry used on the bives with lime, were as dry and clean as when first made. No one will believe the amount of water quicklime takes up by chemical affinity, unless they try the experiment for themselves; therefore, take about 1 quart of it in a basin, and ½ pint of water, which pour slowly on the lime, stiring well all the time during the shiking, and if the lime was prometly made year will have a lime was properly made you will have a perfectly dry powder, still capable of absorbing more water before becoming damp. The action of the lime is three-

1.

It absorbs moisture. It absorbs carbon dioxide (carbonic acid).

3. It gives out a large amount of heat.

This it does slowly, and in exact proportion as it absorbs the breath of the i.e., much moisture, rapid chemition, much heat. What is still cal action, much heat. What is still more strange, this is dry heat, not moist This absorbing action is so slow, and the amount of heat so small, that noth-ing but scientific instruments, hygro-meter and thermometer, and the bees can appreciate the meaning of a constant, mild, dry, pure atmosphere. What is the use in making the bees use What is the use in making the bees use up their honey, worth 15c, per 1b., to develop the requiste heat to keep them alive, when it can be done with lime, worth less than one cent per 1b., and which is almost as valuable after this slaking as before? Do not believe me when I say you are of the 10 colonies. when I say, not one of the 10 colonies above mentioned used over 15 lbs. of honey (all they had) in wintering out of doors, even if it was a mild winter, for can hardly realize it myself, even when see the figures in my yard-book now

before me.

When you try the experiment of slaking the lime, notice the heat developed, but not with you linger (unless for a

absorb much more water than lime, and I expect much from it for these same purposes; but it will have to be contained in a water-proof vessel as it is one of the most delinquent substances I know of. Abscence of actual expriment is the only reason that prevents me from recommending this substance to the careful bee-keeper, although I am certain it would be a success.

#### MISCELLANEOUS.

test One of the most examisite and ancient beverages of Poland, had been elevated even to a drink of the gods in times before Christ. More accurate statements in regard to the manufacture of this drink, date already from the year 1067; at that period it was known under the name of "Sycera," and was considered, according to popular tradition, as a remedy possessing a miraculous power. The preparation is very simple; pure honey is used with a certain quantity of water, which is boiled and after that left to ferment. The older mead becomes, the better it is, and has a taste similar to Malaga or Marsala wine; in using it for abdominal disorders it has a very soothing effect, but when taken in larger quantities it will produce heat and stupefacancient beverages of Poland, had been ties it will produce heat and stupefaction.—German Paper.

THE AMERICAN BEE JOURNAL is the leading apicultural journal in the Union; was heretofore published as a monthly octayo, but now it is changed monthly octavo, but now it is changed into a four-column weekly quarto, and from this time forward will be published in that form. The BEE JOUENAL enjoys the enviable reputation of having been the first periodical exclusively devoted to apiculture in America, and it is at this time the only weekly paper devoted to that specialty in the world! It is a remarkably clean and clear print, on fine calendered white paper, and we commend it to our patrons and the public. Each number will contain eight pages (32 per month) at least an inch longer and wider than the Farmer, and well filled with the most ably conducted bee literature in this or any other counbee literature in this or any other country; and at the end of the year its pa-trons will possess 416 pages of the choi-cest and most reliable bee literature excest and most reliable bee literature extant. We know from many considerations that this "departure" will be acceptable to the old patrons of the Bee Journal (and their names ought to be "legion") not only in America, but wherever the English language can be read, or bee culture pursued. It affords as well-language the result of the patron of the same transfer of us unalloyed pleasure to notice these inus unalloyed pleasure to hottee these indications of progress on the part of our contemporaries, and especially those engaged in illuminating the realm of "beedom,"—Farmer, Lancaster, Pa.

Is there any joy greater than that which is experienced by one person when he helps another? There are some men so low down that it is said they can not bear to have the smell of their clover go into the highway for fear that others will get something that belongs to them without paying for it; others are said to begrudge bees the honey which they take from their flowers without leaving anything behind; but that is, doubtless, imaginary. A man whose heart does not respond to an act of doing good or giving happiness is no longer a man. He has passed the line of manhood, and should be ranked among beasts.—Patron's Guide.

♠ At the Chicago meeting of the National Society we were requested to get photographs of the leading apiarists, to photographs of the leading apparists, to sell to those who wanted them. We can now supply the following at 25 cents each: Dzierzon, the Baron of Ber-lepsch, and Langstroth. The likeness of Mr.Langstroth we have copied, is one furnished by his daughter, who says. was in good health and spirits." We are glad to be able to secure one of such

#### Indiana State Convention.

The Indiana State Bee-Keepers' A sociation met at Indianapolis on Jan. 13, 1881, at 10 a. m.

President Belman in the chair. Many Tresident belinan in the chair. Many members being absent, the regular or der of business was postponed until the afternoon, and after friendly greetings, adjourned till 2 o'clock p. in.

On reassembling, the regular order of

business was proceeded with. The secretary's report being the first thing in order, was read and approved. The treasurer's report showed the total amount of recepts to be \$27.50; expenditures for advertising, postage, etc., \$12.18; leaving a balance in the treasmy of \$15.32.

#### PRESIDENT'S ADDRES

Since our last meeting but little has transpired among apiarists throughout the State, except what is patent to all a general regret that the honey harvest has been, in commercial parlance "short." Everyone present is fully advised as to the causes which produced vised as to the causes which produced this failure, and that against such a re-sult there was no possible remedy. Very many colories tailed to seeme a sufficient quantum for their winter stores, and teeding became necessary. The product for the market was exceed-ingly limited, and instead of the channel ingly limited, and instead of the choice white clover or apple blossom honey, there was sold the full flower or wild exotic honey, not as palatable nor as marketable as the former. Close up to the last working days of the industrious bee, came a cold wave in October from the polar regions, which found very many of our bee-keepers asleep, and the sequel was, the weakening and loss of scores of colonies. In view of this nuusnal state of apicultural affairs, there cannot be expected at this session any encouraging reports as to the financial results of the year 1880. condition of discouraging surroundings in aplarianness may not occur again in a lifetime, while the probabilities are that the approaching season will be grandly successful and productive. Therefore, I give you good cheer and arge you to delve down deep into the facility of aniculture and as you develop fields of apiculture, an L as you develop the mysterious instinct of the bee and its many but certain workings, let it be your highest pleasure to impart all information you may possess to your fel-lows, until the bee-keepers of Indiana shall receive the plaudits of sister states Well done, good and faithful ser-ots." This may be our triumph, pro-

vants.— This may be o ir triumpu, pro-vided we invoke the ordering and guid-ance of an all-wise Providence.— While there is a possibility of too much care in the housing and wintering of the bee from what it would re-ceive in the trunk of a tree or a hole in the ground, there is undoubtedly much to be apprehended in the carelessness and indifference and incompet ney, on and indirected and incompet dey, on account of which many colories are lost, and the amateur, and, indeed, the more experienced, attribute the fault of their mishap and failure to the bees, to the hive, and even the ways of Divine Providence, when to theinselves and none other they should charge the misman-agement and unwise, indolent and inju-dicious handling....

As to the character and comeliness of

As to the character and comenness of your packages, permit me to urge your closest attention, that they may be nearly and carefully prepared, and so presentable for the customer as to command the highest commendation and the best market price. Various methods Various methods the best market price. Various methods have been given in the bee journals and yet much depends upon the aparist as to how far these may be a success. To my thought there is no table condiment so delightful to the eye and palatable to the teste, as honey in uni-form and roundly-formed capped packform and roundry-tormed capped pack-ages. I would recommend that your secretary be empowered to obtain the names and postoffice address of every bee-keeper in the State of Indiana, re-

kind of hive used and such other information as would be useful to the State Association; and to this end that the secretary draw his warrant on the treasmer, countersigned by the president, for such sums as will produce printed circulars, postage, papers, etc., necessary to carry out this purpose....

As to the present status of the Association financially. I refer you to the annual report of Hon. Isaac X. Cotton, treasurer, and also the report of your hstinguished secretary. Mr. Frank Dougherty. The society is not in debt. Dongherty. The society is not in account and has a small balance to their credit in the treasury. There is, in the opinin the treasury. There is, in the opinion of some of the members, a necessity for a change in the price of initiation, or rather an increase from 50 cents to stiper annum. It is urged that a need st per annum. It is arged that a need will arise for additional funds to pay expenses of new projects that may be ordered by you, and which are deemed necessary for the augmentation and furtherance of the interests of the society. I trust such action will be taken

m this regard as will facilitate this end.

I am also impressed that profitable
advantages would be obtained by the
organization of county societies in every part of the State, from which auxiliaries the State organization would receive waluable statistics and other matter beneficial to the apicultural interests of Indiana. May I be permitted to urge upon you the propriety of taking such

steps as will bring about these results?
In closing this hastily prepared address, I must refer with pleasure to the arcss, 1 must terer with pleasure to the very valuable services rendered the api-ary interests by your secretary. Mr. Frank Dougherty. His time has been largely contributed to the advancement and development of the busy bee in diana, and I cordially recommend his re-election to the trust he has so com-mendably and ably filled during the past year.

With many thanks for the honor I with many thanks for the honor I have enjoyed at your hands, Learnestly invoke your continuity and faithfulness in a profession which should be, as I believe it is, the pride of our lives.

After the reading of the address, the After the reading of the address, the convention proceeded to the election of officers for the cusuing year, resulting as follows: President, J. H. Orear, Lizton; Secretary, Frank L. Dougherty, Indianapolis; Treasurer, I. N. Cotton,

Trader's Point.

An essay on " Moving Bees by Railroad," prepared by Rey, M. Mahan, Huntington, Indiana, was read by the s cretary. It contained some valuable s cretary. It condained some variable suggestions in regard to preparing bees for safe shipment. The paper was discussed by several members.

"Wintering Bees," the next question,

was then taken up.

Mr. Belman packed in straw; did not think they could be too well protected.

Mr. Fells used large boxes around ic hives, well filled with dry leaves. and had succeeded beyond his expecta-

The secretary, in wintering, removed all combs that the bees did not cover; thought five or six combs a plenty where care was taken to give those containing sufficient stores. Placed sticks across sufficient stores. Placed sticks across the top of the frames to keep the cloth from settling down, to allow the bees to cross from one frame to another. Used chaff division bourds on the sides, with pieces of carpet, blankets or quilts, and chaff cushions on top. Thought aland chaff cushions on top. Thought almost as much depended on the fall management of bees for safe wintering, as packing. Was satisfied that young bees were almost a necessity; they were better able to withstand the cold and continement than old, half worn-out

Mr. Davis said his bees had been flying out, leaving the hives a few at a time, all winter, until some of the hives had become entirely depopulated, very few dead bees around the cutrance. Mr. Fells thought old bees the cause, with which the president and Mr. Brown agreed. The secretary did not think that this trouble could be entirely attributed to old bees; he believed that there was disease, something which we were not yet able to diseass. Mr. Raab there was disease, sometiming which we were not yet able to discuss. Mr. Raab thought old bees the principal cause, but believed, with the secretary, that there was still a disease at work also.

Mr. Belman, the meeting adjourned till 9 o'clock the next day.

The meeting of the second day was

called to order at 9 o'clock, with President Orear in the chair. After the dent Orear in the chair. After the usual preliminaries, allowing of hills, etc., the convention proceeded to the discussion of various subjects. Albino bees being the first. Mr. Brown believed them to be a distinct race, while the voice of the convention decided them to be a cross from the Italians.

Introducing virgin queens, came next. A majority of the members seemed to think the best plan was to let them run in at the entrance, taking their chances, believing the loss would be no greater than in introducing queen cells

Hiving swarms was discussed at some

The secretary was then called on to describe his mode of making candy for bees, some samples of which seemed to please the bee-men as well as bees, from the manner in which it disap-

Various other interesting subjects various other interesting snoperts were then discussed at some length, when the question of vice-president was called up. After some discussion it was decided to nominate a vice-president for each county, instead of each Congressional district, as heretofore. Congressional district, as aerecords. The list not being completed, the executive committee was instructed to fill vacancies and notify the appointees, G. J. Brown, Anderson, Ind., read an

essay on "Bees and Bee-keeping."
The secretary was instructed to have constitution and by-laws printed, sending one copy to each member of the so-

Association, by resolution, returned a vote of thanks to Secretary Heron, of the State Board, the Board of Agriculture, and the daily papers, for favors received.

There were on exhibition many samples of implements used in modern becples of implements used in modern occulture, among which were two extractors and knives from C. F. Muth, Cincinnati, Ohio, and G. P. McDougall, Indianapolis; honey-knife and smokers, from Bingham & Betherington, Otsego, Mich.; Quinby's New Smoker and book, from L. C. Root & Bro., Mohawk, N. Y.; A B C of Bee-culture, and Cook's Manual of the Apiary, from the Indiana Farmer office.

The secretary also had two hives. The secretary also had two lives, showing the different styles of sections, queen eages, candy, etc., all of which were much admired by the members.

The convention adjourned to meet at

the call of the executive committee.
FRANK L. DOUGHERTY, Sec'y.

#### Texas Convention.

The Texas Bee-Keepers' Association convened at Greenville, Hunt county.

Jan, 11, 1881, at 1 p. m.

Judge W. 11, Andrews, president, de-livered a brief address. He was well pleased with the interest taken in beeculture by the few who were engaged in the pursuit. He said that to be suc-cessful in bee-culture one must take an interest in the study of the habits and natural history of the honey bee; that hee-keeping was a progressive science, that there was much to be learned; and that by an interchange of ideas, such as was to be had in our conventions, was both useful and instructive as well as pleasant and interesting. He had har-vested an unusual crop of honey during the past season. He commenced the season with 425 colonies and increased 10 200, which went into winter quarters in good condition; after having produced between 7,000 and 8,000 lbs. of honey, mostly in the comb. He had hitherto believed the blacks to be the easiest to induce to work in boxes, but the past season demonstrated that his best Italians were equal, it not superior to any; he assigned as a cause, in the past, of failure to induce his Italians to commence in boxes,—disturbances accasioned by queen rearing.

Mr. John Mason, on a recent visit to Arkansas, had discovered that "black gum" yielded an abundance of honey, of excellent quality. He commenced of excellent quality. He commenced the season with 53 colonies, and had in-creased to 80; all of which were in good bec-keeper in the State of Indama, requesting from them the number of their questing from them the number of their colonies, amount of honey produced, in until quite late, when, on motion of above the brood chamber. One that he

weighed, showed \$3 lbs. The honey left over was pungent and not fit for the market, or any other purpose, unless it was for some medical virtue it might possess. He had extracted a few pounds of it, found that it granulated readily. of it, found that it granulated readily, but did not lose its pungency. He had obtained 1506 lbs. of extracted and 600 lbs. of comb honey. He sold the extracted at 16½ cents per pound and the comb honey at 20 cents. The comb honey was all in boxes, which were emptied and returned. He sold his honey at home. His honey was the best had been all that could be wished.

Mr. W. R. Graham was wall ideased.

Mr. Wm. R. Graham was well pleased Mr. Wm. R. Graham was well pleased with what his bees had done during the past season; he thought it had been the hest, in this locality, for years; he had 10 colonies in the spring, and increased to 100. He noticed that, late in the fall, some of his bees had no brood, but had plenty of honey. He obtained 2,000 lbs, of extracted honey, which he sold at 15 mays tearly, at home.

15 cents per lb., at home.
D. W. Yeager, commenced the season D. W. Yeager, commenced the season with 8 colonies and had an increase of 14, making in all 22. He had 360 lbs, of extracted honey. The nicest he had ever seen. His increase was by artificial swarming entirely. His bees were shaded by his vineyard.

Dr. Wm. R. Howard commenced the season with 20 colonies, after having lost 2 from dysentery, early in the spring; had increased by natural swarming to 43, which were all alive the last warm day, when they had a fly. He had taken 750 lbs. of extracted honey. had taken 60 lbs. of extracted noney, of fine quality, which he sold at 15 cents per pound, mostly at home. What was put on the market, was put up in ½ gal, glass fruit jars. He had spent a good deal of time in Italianizing his apiary, and breeding a good strain of bees. The year 1878, he thought, was as good a honey season as 1880, and that the reanoney season as 1880, and that the reason that such enormous yields had been harvested, the past season, was that all hands had plenty of comb to give to swarms, comb left over from the serious losses in 1879. That neither Mr. Gra-ham, Mr. Mason or Judge Andrews had made up in numbers, the colonies for

All agreed that that was a great help, but thought that last year was the best

for several past.

Or. Duff said that he commenced the balls on with 1 colony, and had increased to 5; he received about 30 lbs. extracted honey, and was well satisfied with his success, considering the capital in-

success, considering the capital invested.

Dr. D. J. Jernigan wanted to know if any one had tried the Spider plant and Simpson's honey-plant; he had raised a few plants and had seed of the spider plant to give to any one who wished to try it.

No one had any experience with aither of the plants but from what some

president, de-He was well had seen of the plants, but from what some had seen of their honey-producing qualities, were satisfied that they were val-uable and would be made useful, if it were not for the difficulty in starting

the plants.

Dr. Howard had planted an acre in buckwheat in 1880, and, though the bees visited it every morning, he received no honey from that source. He ceived no honey from that source. He had tried buckwheat in 1879 and 1880, and had succeeded in getting a good crop of seed and straw, growing as high as 6 ft., both years, and a considerable amount of honey from it in 1878, considering the number of bees he had to gather it. He had plants enough to set anacre of sweet clover or melilot, which he would try the coming season; some he would try the coming season; some of it blossomed the first year from the seed. He thought the acreage of horsemint was steadily increasing; as the grass was being eaten out on the prairies and rapidly giving away, horsemint was taking its place. All agreed that horse-mint was the plant of all plants for honey.

On mation a vote of though was too

On motion, a vote of thanks was ten-dered to Messis. Matthews and Marshall for the use of their spacious and com-fortable room in which to hold our confortable room in which to hold our convention; after which the incetting adjourned, to hold its 3d annual convention at the apiary of Indge W. H. Andrews, at McKinney, Collins county, on the 12th and 13th of May, 1881.

W. H. Andrews, Pres.
WM. R. Howard, Sec'y.

#### CLUBBING LIST.

We supply the Weekly American Bee dournal and any of the following periodicals, for 1881, at the prices queted in the last column of figures. The dirst column gives the regular price of both:

#### Honey and Beeswax Market.

RUYERS' QUOTATIONS.

#### CHICAGO.

CHICAGO.
HONEY- The market is plentifully supplied with honey, and sales are slow at weak, easy prices. Quotable at 186-29c, for strictly choice white comb in 1 and 2 lb. boxes; at 146 for, for fair to good in large packages, and at 106 12c, for common dark-colored and broken lots.—Chicago Times.

BEESWAX.—Choice yellow, 20@24c; dark, 15@17.

#### NEW YORK.

HONEY.—Best white comb honey, small neat packages, 186 30c; furr do., 156 lbc; durk do., 1164 large boxes sell for about 2c, under above. White extracted, 36 lbc; dark, 768c; southern strained,

BEESWAX.-Prime quality, 20\(\alpha\) 24c. H. K. & F. B. THURBER & Co.

#### CINCINNATI.

HONEY.—The market for extracted clover honey every good, and in demand at lic. for the best, and ose, for basswood and dark honey. The supply of omb honey is good, with a fair demand. We pay 6; for the lest. Sc. for the best. BEESWAX-18@24c. C. F. MUTH.

#### SAN FRANCISCO.

SAN FRANCISCO.

HONEY-Our market is inactive for boney-no demand only for local trade. We quote comb 12a/4c.
Extracted, choice white, 7a/2c.; off-colors and canded, 5a/bac.
BEESWAX-22a/2c., as to color.
SPEARNS & SMITH, 423 Front Street.
January 22, 1881.

# Books for Bee-Keepers.

Cook's Manual of the Aplacy. Entirely rewritten, greatly enlarged and elegantly illustrated, and is fully up with the times on every conceivable subject that interests he amartst. It is not only in structive, but intensely interesting and thoroughly practical. The book is a masterly graduction, and one that no beckeeper, however limited his means, can afond to do without. Cloth, 81-25-7 paper covers, \$1.09, postpand. Per dozen, by express, cloth, \$12, paper, \$2.0.

Oninby's New Ree-Reeping, by L.C. Root.
The mither his treated the subject of lee keeping in a minner that cannot full to interest all. Its style kylain and toreible, making all its renders sensible of the fact that the author is really the master of the subject. Pinc. \$1.50.

Navice's A It Coffice-Culture, by A. I. Root, his embraces "everything northing to the care of this embraces "everything perfaming to the care of he honey-bee," and is valuable to beginners an hose more solvanced Cloth, \$1,25; paper, \$1.00.

King's Rec-Keepers' Text-Rook, by A. J. King This edition is revised and brought down to the present time. Cloth \$1.00; paper, 25c.

Langstroth on the Hive and Honey Ree This is a standard scientifle work. Price, \$2.00.

Blessed Bees, by John Allen.—A romance of bee-keeping full of practical information and con-tagious cuthus as in. Cloth, \$1.00.

lagious cultius as in. Cloth, \$1.005.

Rec-Cultiu et or Successful Management of the Aniary, by Thomas G. Newman. This pampillet enhances the following subjects: The becation of the Aniary—Briner Plants. Queen Regring—Feeding Swarmurg Dividing Transferring-Italianizing Introducing Queens. Extracting—Quieting and Dandling Recs. The Newest Method of Preparing Homey for Mirrkel, etc. It is published in Engits and German. Price for either edition, 40 cents, postpind, or \$3.00 per dozen.

Food Adulteration; What we cat and should not cat. This book should be in every family, where it ought to create a sectiment against the adulteration of food products, and demand a law to protect consumers against the many health-destroying adulterations offered as food. 200 pages. Paper, 50c.

The Hzierzon Theory; -presents the funda-mental principles of bee-culture, and furnishes a condensed statement of the facts and arguments by which they are demonstrated. Price, 15 cents.

which they are demonstrated. Price, 15 cents.

Honey, as Food and Medicine, by Thomas G. Newman.—This is a pumphlet of 24 pages, discoursing upon the Ancient History of Bees and Honey; the nature, quality, sources, and preparation of Honey for the Market Henry is an arrele of food, giving troinin, Wines, &c.; and I honey as Medicine, followed by many neeth Recipes. It is intended for consumers, and should be scattered by thousands all over the country, and thus assist in creating a demand for honey. Published in English and German. Price for either edition, Ge.; per dozen, 50c.

Wintering Bees.—This pamphlet contains all re Prize Bssays on this important subject, that were ad the fore the Centennial Bee-Keepers Associa-ion. The Prize—42 in gold—was awarded to Prof. ook's Essay, which is given in full. Price, 10c.

Hees and their Management. This pamphlet was issued by the Italian Bee Company, and has had a large circulation. The price has been reduced from 20 cents to 10 cents.

The Hive I Use-Being a description of the hive used by G. M. Doolittle. Price, 5c.

Kendail's Horse Book - No book can be more assetul to horse owners. It has \$5 engravanes, Illustrating positions of sick hoses, and treats all diseases in a plant and comprehensive manner. It has a large number of good recipes, a table of doses, and much other valuable borse information. Paper, 25c.

Chicken Cholera, by A. J. Hill,—A treatise on its cause, symptoms and cure. Price, 25c.

Moore's Universal Assistant contains information on every conceivable subject, as well as receipts for almost everything that could be desired. We doubt if any one could be induced to do without it, after having spent a few hours in looking it through, it contains 480 pages, and 500 engravings. Cloth, \$2.50.

Ropp's Easy Calculator.—These are handy tables for all kinds of merchandise and interest. It is really a lightning calculator, nicely bound, with state and packet for papers. In cloth, \$1.00; Morocco, \$1.50. Cheap edition, without slate, 50c.

#### SPECIAL NOTICES.

Premiums.—For a club of 2, weekly we will give a copy of "Bee-Culture; for a club of 5. weekly, we will give a copy of "Cook's Manual," bound in cloth; for a club of 6, we give a copy of the Journal for a year free. Do not forget that it will pay to devote a few hours to the BEE JOURNAL.

"What is the meaning of 'Dec. 81' after my name on the directionlabel of my paper?" This question has been asked by several, and to save answering each one, let us here say: It means that you have paid for the full year, or until "Dec. 31, 1881." "June 81" means that the first half of the year is paid for, up to "July 1st." Any other month, the same.

Owing to my increased business I shall not be able to attend to the bee supply business this year, and while thanking all my old customers for past favors, I would recommend them to buy their bee-keepers' supplies from Mr. A.
II. Newman, of Chicago, as I know the orders will be despatched on the shortest notice.

THOMAS G. NEWMAN,

The foremost religious newspaper of the United States."-Joseph Cook. - :0::-

THE INDEPENDENT seeks the paironage of the public on three grounds, as follows:

1st. It is the largest weekly religious newspaper published in the world.

5d. It employs as contributors more able writers, at home and abroad, than any other weekly newspaper.

3d. It gives its readers a wider range of topics and more and fuller depart-ments than they can find elsewhere in any journal.

any journal.

THE INDEPENDENT consists of 32 pages, neatly cut and pasted. It is printed from clear type (we stereotype the pages weekly, and, hence, every issue is really printed with new type) and on good paper, and mechanically it is unexcelled.

There is no Question of prominence in religion, politics, science, education, finance, or any other department of human knowledge which THE INDEPENDENT does not discuss. It has regular departments devoted to Biblical Research, Missions, Religious Intelligence, Book Reviews and Literary News, the Sunday school, Education, Science, Sanitary questions, Fine Arts, the movements of ministers. Personablies, News of the week. Financha and Commercial matters, inclining Weekly Prices Current, Market Reports, cattle Market, Dry Goods Quotations, Flowers and Farming, and Instrance. In the first proposed pages of stories and poems adapted to Old and Young are given every week, with a column of Puzzles.

From time to time Sermons by eminent ministers are multipled.

From time to time Sormons by eminent ministers are published. The current topics of the day are discussed in our editorial columns freely and vigorously. We are not atraid to state our opinious.

For the American Bee Journal

#### The Weekly, Introducing Queens, Etc.

G. H. ADAMS.

As I have been a reader of the American Beil Journal and a keeper of bees for over 3 years, I thought I would express myself in regard to the Journal. I like it very much and cannot do without it. Friend Newman, you may put me down as a life subscriber of the American Bee Journal. I am glad it is to be a Weekly. I think \$2 a year very low for a weekly bee paper. I will say I think there is just one article in the December number, p. 565, written by Mr. G. M. Doolittle, "Plenty of bees; plenty of honey," that is worth the whole amount of the subscription to beginners, let alone all the other good articles. the other good articles.

As I have not sent in my report for 1880. I will now do so. I opened the season with 40 colonies of bees; 12 of the number were good, strong colonies—the others were very weak. The 12 gathered 700 lbs. of comb honey; two of the twelve, where I could side-box, thereby getting on 68 2-lb. sections at once, obtained for me 250 lbs. I had 100 lbs. of honey stolen off the hives this last fall. My honey sells readily for 20c. lot los, of noney stolen off the filves this last fall. My honey sells readily for 20c. per pound, it being mostly white clover and goldenrod. The other weak colonies being in fine condition for winter, and what is best of all, are all Italianized. I have but 2 black colonies in my apiary. My colonies in correspond from 10 to 61.

dation from other hives and place the brood in other hives in their places. Close the hive and in a few minutes great excitement will prevail in the hive, rushing out and up the sides of the hive in wild confusion. Now drop the queen right among the bees, and the excitement will immediately stop and the queen will be earlest introduced. the queen will be safely introduced. I have introduced several valuable queens by this method with success. Of course, you must always wait until this excitement prevails and success is certain. North Nassau, N. Y., Jan. 5, 1881.

For the American Bee Journal.

Our unusual heavy frosts have kept it was in September, 1879. Our unusual heavy frosts have kept it back. The rains are backward, and the new grass has just begun to make its appearance. My bees are in good condition, but colonies are not large. I have not extracted any honey since June; have plenty of goldenrod honey for wintering. I save all my dark honey in the frame, and keep it for wintering. Woths are destroyed by funigating with Moths are destroyed by funnigating with sulphur. I consider it a better way to melt up empty comb and give foundation in the spring. My cappings furnish me with enough wax, with what old comb I melt up, for my own use without larging.

We had a very short season for sur-Two Queens in One Hive, etc.

1. D. ENAS.
The December number of the American Bee Journal notices two queens in one live. I was at the Mechanics Fair, at San Francisco, last August and September, for three weeks. When I returned home, as soon as convenient, I examined several hives. One had a week soon where the had a very short season for surplus in this neighborhood. With 47 colonies in the spring. I obtained about 1,800 lbs. of extracted and 350 lbs. of comb honey, and have 100 Langstroth frames of goldenrod, all sealed over, for the dimensional section of the spring. I obtained about 1,800 lbs. of extracted and 350 lbs. of comb honey, and have 100 Langstroth frames of goldenrod, all sealed over, for the dimensional section of the spring. I obtained about 1,800 lbs. of extracted and 350 lbs. of comb honey, and have 100 Langstroth frames of goldenrod, all sealed over, for the dimensional section of the spring. I obtained about 1,800 lbs. of extracted and 350 lbs. of comb honey, and have 100 Langstroth frames of goldenrod, all sealed over, for the dimension of the spring. I should be sufficient to the spring of the sp

recommend it to others, especially to a novice.

I find that the Langstroth frames mold here in the winter, and they hold too much for comb honey, so I have made hives this season 2½ in. shorter in length of frame, which give me better satisfaction. I use the same surplus apartments; have no portico, but the front projects about 3 inches. The hives are ready for surplus sooner, and the bees are forced into the sections sooner. To illustrate: I had a swarm come off on the 13th of May, 1880; the queen, with clipped wing was on the ground. I removed the hive to a new stand; as soon as bees were out I put a queen, with elipped wing was on the ground. I removed the hive to a new stand; as soon as bees were out I put a new hive on that stand; gave them one frame of brood and stores, 2 frames of stores in drone comb, and 7 empty frames. On the 15th, I took away 20 empty frames, placed 2 of drone comb in each side of the hive, and the 7 frames of foundation (full sheets). In just 7 days, on the 22d of May, at the entrance, something looked suspicions. Expecting to see the foundation on the bottom, I opened the hive, and found the foundation all built out, full of honey, and nearly capped over; I took out 5 frames, gave them 5 empty combs, and put on 27 sections,  $5\frac{1}{2}x6x11\frac{1}{2}$ . Just 3 weeks from that time. I took off 21 sections, solid, and 5 frames sealed over; the other 6 sections from  $\frac{1}{2}$  to  $\frac{3}{4}$  filled; but as the honey flow was cut short, I gave them to other colonies. I abstrate when 75 the other force from  $\frac{1}{2}$  to a photography of the proper frames and other forces from  $\frac{1}{2}$  to  $\frac{1}{2}$  when the other observable from a to 4 tilled; but as the honey flow was cut short, I gave them to other colonies. I obtained about 75 lbs. of honey from this colony, of superior quality. I did not sell any of my honey until October, and shall dispose of all of my surplus at fair prices, and my honey has a good reputation. I have to compete with honey, repacked, at the fruit factories, at San Francisco, and labeled "Orange Bloom Honey." Perhaps all the orange is on the label. Wherever I can leave a sample, I do not fear for the result. I use the best of machinery, even if f have to pay high express charges to get it, and my honey is clean and pure. I have it in different styles of packages, and even on draught, to suit different customers. customers.

It is difficult to save empty combs here, as moths will breed, I think the whole year; but in the hives that I use, my bees will keep the combs free from moths, even if they do not cover  $\frac{1}{4}$  of them them.

Napa, Cal., Dec. 13, 1880.

#### Bees Dying in Indiana.

E. C. FARQUHAR.

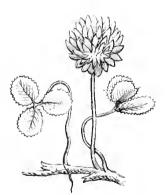

In the the spring of 1879, I bought 2 colonies of bees in box hives, transferred about which queen was in that hive. rain. Owing to sudden and frequent The first week in December having ocand what is best of all, are all Italianized. Casion to look over the hive, I found the young queen with perfect wings. My colonies increased from 40 to 64; apparently all right, and at home on the young queen with perfect wings. By the shape, I should judge that is their winter quarters. In the spring chaff, I sold 5 Italian queens.

Now, I will give my method of packing in chaff. I sold 5 Italian queens.

Now, I will give my method of introducing queens, which I have discovered and adopted as the only true method. It is this: Take the queen from the hive youn wish to introduce another took worm-dust from an old decayed tree, as the substitute for pollen. I find very little vacancy with combs of honey or foun-

Melilot or Sweet Clover.

White or Dutch Clover.

young queen; I supposed at the time that the old one was superseded; in about a fortnight after, I did not find her, as I supposed, but found a queen with only one wing, the other gone entirely. I supposed it to be the old queen. I make a practice of clipping one wing, as soon as proved to be laying, although I leave at least a half; but she had wings on only one side. Her color was duller than the young one, when I observed her before. I was in doubt about which queen was in that hive. The first week in December having occasion to look over the hive, I found

On account of the late and cold rains, queen-cells were cut down by the bees, and in one instance I found 8 queens in a first swarm. The old queen was superseded. I saved 7, one was killed in the cluster, and I had to do considerable work in a heavy drizzling rain. Owing to sudden and frequent showers, many of my cells were hatched in an incubator, and I even had to keep them and feed them several days for clear weather. I lost a good many virgin queens on that account in introducing them.

months to attend to my bees, while I made lives and attended to the farm necessities. My expenses for the season, for hire and material, was about \$115. my income for hives, transferring, &c., was about \$103. I have on hand hives and lumber worth \$70, empty vessels for extracted honey (which I did not get). for extracted honey (which I did not get), worth \$7. So, you see, my time and labor was not all loss. I have a shop 14x20 ft, square, with a room up-stairs. At the back, or east side of the shop, is a shed extending 54 ft, east, and 10 ft, wide, high enough to walk under. Here I have my bees arranged in 2 rows, fronting north and south, on trestles 6 in, high. This makes an aisle 4 ft, wide between and at the back of the hives, so the passing bees do not interrupt me in the passing bees do not interrupt me in handling them. This fall when prepar-ing them for winter. I turned the north row to front the south, and weather-boarded the north side and east end of the shed, the shop forming a wind-break

I was sick in the fall, run behind with ny work generally, and did not get to prepare my bees for winter until after the cold spellin November, and I found the cold spell in November, and I found several colonies dead. Bees are dying in this locality badly. They seem to have a dysentery, I think I will lose my entire stock. I have I Italian queen which I bought of W. O. Pearce, Winchester, Ind., he said he bought of T. G. Newman & Son. She is a fine queen, gentle and profific. I also reared a few yeary fine queens from her last summer. yery fine queens from her last summer; but I fear I will lose all, for they are dying in every hive. I have a thick woolen absorber over each colony, but the trouble seems to be impure or unhealthy honey, causing a dysentery.

Since writing the above I have seen some more of my neighbors who had a few bees, but all were dead but 1 colony.

Another man had something over 60

colonies, all were dead but 2 about 2 weeks ago.

Trento, Ind., Jan. 1, 1881.

For the American Bee Journal.

Lower Ventilation, Adulteration, Etc.

WM. CAMM.

Let me say to friend Shuck that I used a much finer mesh, in the wire I put over my lower ventilators than he recommends, for I was atraid of giving the moth-worm a chance to get through and build its cocoon under the bottomboard. It seemed so distasteful to the bees, as they waxed it all up at once, that I gave it up. By all means our best way would be to so pack, or wrap up the hives, as to prevent condensation, and subsequent gaugestation. tion and subsequent congeniation of moisture. Where hives are double, like moisture. Where hives are double, like the Armstrong, for instance, ventilation of the outer case is sufficient in the hottest weather, and with the entrances wide open, I have had such a hive stand in the broiling sun and not a comb melt down, though all around and about the frames and sections was air-tight, as the bees always make it if they can; and I think we ought to be guided by and I think we ought to be guided by the instinct of the bees themselves in this matter. The bees seal up every-thing they can, except the entrance, about that part of the hive that is im-mediately about them, and outside of that man should use his skill and in-genuity. There is much about what we cell outside the transport of the transport in the transport of the transport gening). There is much along what we call animal instincts that we have not fathomed yet, and 1 am loth to force upon my bees a condition against which they so persistently rebel. Pitch up the eyes of a bat, and yet he can fly safely in a room where there are many objects for him to strike against; throw a squirrel from a height of several hundred fect with only jagged rocks to jagged rocks to alight on, and be will suffer no barm; so when I see my bees so stremously try to stop all lower ventilation, I conclude that it is something else that is required. not that.

Though I do not believe that any

the foundation of our social system, and our laws, we have unfortunately made two very great mistakes; we recognize gain as legitimate where there can be no natural increase, and we recognize no wrong, no violence to humanity, in trafficking and speculating in that which sustains human flesh and blood. though we call trafficking and speculating directly in huntan flesh and blood slavery; yet so far as results are concerned, the effect is the same. Correct these fundamental errors and the spoils being no longer to the shrewdest, adulteration, with many other sins, will disteration, with many other sins, win dis-appear. There are plenty of other papers in which questions of this kind can be discussed, and 4 only refer to it here because it is relevant to the sub-

Bees have had one or two short flights in the last two months, and a week ago one of my lightest colonies, in a single-walled hive, unprotected, were at home and cheerful. This colony has been dropping fresh brood upon the bottom-

board all winter.

1 am much pleased with the change from the Monthly to the Weekly, and hope that you will find it profitable and pleasant to continue it in this shape.
Winchester, Ill., Jan. 22, 1881.

For the American Bee Journal.

#### Size of Colonies, Ventilation, etc.

E. B. SOUTHWICK.

I notice in the report of Mr. E. A. Morgan that he thinks 3 pecks of bees a good colony, and that each of his 24 colonies would measure that amount. Now my frames are 12x13 inches. I place them 3<sub>8</sub> of an inch apart, when the frames are full of brood or honey it would take a hive of 27 frames to hold that amount of bees—just three times as large as my hives are. Is not his statements a little large. I believe that bee-keepers consider that if they have bee-keepers consider that it they have a strong colony of bees that cover 9 frames, the size of mine all over, in the working season, they have a strong a strong coron, frames, the size of mine an over, working season, they have a strong working season, they have a strong when bees are working in a colony. When bees are working in a colony, when bees are working in a colony, when bees are working in a colony. colony. When bees are working in a hive they require at least twice the room they occupy when clustered together in a measurable form. So really a good colony is about 4 quarts of bees. My opinion of colonies is that a peek of bees constitutes a very strong colony;

that 4 quarts is a fair sized colony; that 2 quarts is a small colony, yet not too small to be safely wintered in a judi cionsly arranged hive. I have wintered many such colonies, crowded on 4 many such colonies, crowded on 4 combs, and found them as profitable as

any I had,
I notice in another place a very excelent article on wintering, by the same author. It is first-rate, though rather expensive. I think there is one mustake in it, about appeard ventilation. He says the impure air being carbonic-acid cost and heavier them air will settle to gas and heavier than air, will settle to the bottom and escape. This is true, were it pure carbonic-acid gas. Now were it price carbonic-acid gas. Now let us see what are the facts in the case; The air is composed of 20 parts of oxygen to 80 parts of nitrogen; chemically united it always carries with it a quanticy of water in the form of vapor and some other matter that, we will not notice. Now as air is drawn into the and some other matter that we will de-notice. Now, as air is drawn into the lungs the oxygen unites with the carbon tungs the oxygen unites with the carbonic of the blood, forming carbonic-acid gas, which is absorbed by the mixture in the form of vapor, and mixed with the 80 parts of nitrogen, forming a in the form of vapor, and inixed with the 80 parts of nitrogen, forming a chemical mixture which, when breathed out is much lighter than air and is found in the upper part of the hive in the form of frost or water, unless we have an upward ventilation to allow it to pass off. I would not recommend placing a an upward ventuation to anow it to pass off. I would not recommend placing a storepipe over the bees to left this pass through, but rather a thick chaff-cushion which will allow this foul stuff to pass

which will allow this four stuff to pass into it if not through it and not admit the warmth of the bees to pass off.

I notice in an article by D. K. Boutelle, his experience with some eggs of the queens; if he is correct does it not

when I had them all transferred and the article they buy is genuine. The dieve that the sex of all the animal king-aerate thoroughly more than one or two straightened up. I had 31 colonies. I great and final remedy for adulteration dom is regulated by the situation and spaces. Only from the bottom, where worth naming. I hired Mr. Cramer 212 cheating and many other crimes. In says it is not? There are many theories spaces be equally aerated. These old about bee-keeping which we may make doubtful.

Mendon, Mich., Dec. 10, 1880.

For the American Bee Journal. Upward Ventilation.

F. H. MINER.

I believe I was the first writer in this country to oppose upward ventilation, in discussions with Mr. Baldridge and others in the BEE JOURNAL and Prairie Farmer. A storm of magnation was aroused, but annost every man had seen bee-trees, and knew they had tight tops to keep out the storm and keep in the heat. The united and learned array of acknowledged authorities lost their prestige; facts could not be set aside by theories. Only those who had that "dangerous thing, a little learning," were wild chough to ignore instinct and sneer at nature. Any body may preach at them now, but they still persist in covering bees with porous cloth, depriying them of heat and water, essential to ing them of heat and water, essential to hie. The bees do not tolerate this stu-pidity, but glaze them over whenever they can.
When I read Mr. Langstroth's direc-

tions to give the bees a little water on a sponge, I thought they glazed the inside surfaces, and the cond that commed them condensed the water that they needed. But II we cover them with porous absorbents (coth) the water may be needed (see JOURNAL, page II).

The swarm of five inventors, while the waves of obtivious are rolling over their constructions, delight to sneer at the old log gums. Each one has found perfection, but every 2 or 3 years repu-mates his old humbugs, gets up a new one, and only gets out of the mud into the mire. I loved bees, and laid awake nights contriving a hive, and found that I aid not know anything. In my despair the thought occurred: the light of the bees to the hollow tree proves they were designed for and adapted to stances and necessities require artificial adaptations. We should not use gnms. we must go to nature for principles, and respect instruct.

There are here a few old bee-keepers

who raise their files from  $\frac{1}{2}$  inch to 2 menes, on blocks, to get rid of the moths. I thought they would be too cold and exposed to mice and robbers. the pottom. I bought some of my bees of Simeon Burkett, 5 miles north of Watseka. Last spring he had 90 colomes in good condition, and says they wintered well the year before when so many (more than three-tourths of the bees in this county) died, mostly smothered, having no ny-holes in the side, only notches cut with a saw in the bottom. Severe cold and contraction, for-lowed by excitement and expansion. outlets closed, no air to generate heat, profuse perspiration condensed and irrezing with dead bees at the bottom. One man with 22 colomes, another with 30. lost all; several others nearly as bad. But the bees on blocks came through and kept dry. The mice got in some, and some were robbed.

They should have been set down on the approach of spring. Bees need very fittle air when quiet in mild weather, and keep fly-holes clear. I wintered 48 on the summer stands without loss, covered with snow in the coldest weather; 3 or 4 lailed through loss of queens in the spring. These bees are doing well the spring. These bees are doing the spring. The lives are 1 foot square, out those I bought from Mr. Burkett were tall, populous ones; the holes I bored in front were not large enough tor so many bees in such severe weather, and I have lost 2 colonies, and a good many bees in others. So, let us give our bees plenty of lower ventilation.

I suppose 10 or 15 times as much air

is needed in a cold snap, because 10 or 15 times as much heat must be genera-

spaces be equally aerated. These old basswood-gummen, who believe in tight tops and hate frame hives, never read the Journal and could not know much. the JOURNAL and could not know much. In a futile attempt to get rid of the moths, they simply blundered on a successful method of aerating their bees, and thus preventing smothering. If they knew they had solved the problem so many have studied in vain, would they not crow? They have mythanks. I thought so much cold air would freeze the heas but find it the only thing to the bees, but find it the only thing to keep them warm and dry, thus preventing their being poisoned by a mass of rotting bees under them. They should be protected from the wind. An inch at the bottom all around would not lose as much heat as a ½-inch hole in the top.
I expect to hear of great losses this

winter from smothering. In 1878 I win-tered 48 colonies on their summer stands, in hives with tight tops, and covered with snow in the coldest weather. The last 2 years have been poor. My square hives have been all right, but the tall hives—18 to 24 inches high—the small hole I put in the side was too small in

severe weather. Crescent City, Ill., Jan. 17, 1881.

For the American Bee Journal.

#### Shall we Improve our Bees?

HENRY ALLEY.

Now that we have the Italians, Cyprians, Holy Land and Hungarian races rians, Holy Land and Hungarian races of bees, it strikes me that our bees can be improved very much. How best to do these things is the question. Can it be done by keeping the imported stock pure, or by crossing? I think it can be done by both plans.

It is a well-known fact that by crossing up fowls we get a larger, as well as a burdier race; now this same principle.

a hardier race; now this same principle applies to most everything in the animal kingdom. In rearing chickens the male should be changed for each sucmale should be changed for each succeeding brood. In-and-in breeding would soon run out a coop of fowls; they can be bred "to a feather" by inbreeding, but that quality would be at the expense of health and hardiness. Now, this must work the same with bees; but I must confess the fact that there are cases that seem to knock my theory into pieces. I have found farmers who have kept bees in the same place upwards of 40 years, without any indications of deterioration. I found one such last fall. I came across a man who had 10 colonies of bees, all black, who had 10 colonies of bees, all black, and in old box-hives, as a natural consedud in the observes, as a natural consequence. He told me that he had kept bees in the same place over 40 years; and had never been out of them during and had never been out of them during all that time, and he could not say that they had ever returned him any heavy income. Of course they did not pay him much, neither did he devote much time or expense on them. He had one swarm early in May last, and remarked that he never had one so early before that he never had one so early before. that he never had one so early before. Now, these are stubborn facts, and rather against our in-and-in theory. But it should be remembered that not as much in-and-in breeding would be done in this case of 40 years' standing as an extensive queen-breeder could do in 2 years; while the old farmer would not years more them one ungent to each

in 2 years; while the old farmer would not rear more than one queen to each colony each year, the queen-breeder would rear hundreds.

Notwithstanding the above facts, I do believe that close breeding will ruin any race of bees. Now, in all my experience in rearing queens, I never permitted the queen that I was breeding from to rear any drones. I have reared 3,000 queens from one mother, and never saw a drone from her, and none were ever raised from her eggs. If good queens are what we want, then of course the less in-and-in breeding the course the less in and in breeding the

Will it do to cross the pure Italians with pure Cyprian or Holy Land queens? I think it will; in fact, I know it will. The way is now open so that we can obtain a superior race of bees; by careful breeding and crossing-up the desid-Though I do not believe that any amount of direct legislation against adulteration will avail much, yet tokeep the matter before the people will put them on their guard, and they will be them on their guard, and they will be chary of buying unless they are sure accord that power to the queen. The ranges of comb attached at the top and sides divide the room into narrow spaces. A hole in the side might not the Holy Land and Cyprian bees been that any amount of direct legislation against telle, his experience with some eggs of the queens; if he is correct does it not the queen does not regulate the queens; if he is correct does it not the file times as much heat must be generated to maintain a living temperature. The ranges of comb attached at the top and sides divide the room into narrow the Holy Land and Cyprian bees been in-and-in bred as well as the old farmer's above alluded to? Of course they have. The natives of the Holy Land and Cyprus Island care nothing about improved bee-keeping. If these bees, in their native country, are superior to ours, then we can improve them, without doubt, so that they will be much better. Does not the reader see that by crossing these races we can improve them? Of course he can see it; and believe it, too.

believe it, too.

If it were not for the honesty and reputation of the dealer, many of those who have purchased Cyprian and Holy Land queens would say that they are beautitul Italians, and nothing more. The keen observer and practiced eye will discover the peculairities of the Cyprian bees, even though they look and annear like pure Italians.

appear like pure Italians.
I think I can perfect a race of bees tunnk I can perfect a race of bees the coming season that will be superior to anything we now have; in fact, I now have some queens that are very large and handsome as well as unusularge and handsome as well as unusually prolific—a cross between the pure Cyprian and Italian. I cannot say about their working qualities, as they have had no chance to do much since they came into existence in August, 1880. Now, I am intending to rear queens from these improved mothers to introduce into my own colonies. They will pass for pure Cyprian or Italian queens; few can tell the difference. If these queens will lay eggs in proportion to their size, it will be necessary to enlarge the Langstroth hive to twice the usual dimensions. These queens are the result of careful breeding and crossing.

The reader will see I am in favor of crossing the Italian and Cyprian. Who can doubt for a moment that by crossing with pure Cyprian and Italian bees that with pure Cyprian and Italian bees that we cannot get a superior class of workers? By crossing weshall undo in-and-in breeding that our bees as well as the Cyprians, have been subjected to for years. Remember, that the bees to be crossed should be selected from our best, purest hand-omest and most | r - life. Now here are my ideas for improving our bets. If any man his better way, let him rise and say so best, purest hand-onest and most life. Now here are my ideas for proving our bers. If any man h better way, let him rise and say so. Wenham, Mass.

For the American Bee Journal.

#### Giving Bees Water in the Cellar.

E. A. THOMAS.

Several years ago I had 3 or 4 colonies get very uneasy in the cellar during the latter part of winter. I tried to quiet them by giving them more ventilation, but it was of no use, they continued to grow more and more uneasy towards spring. The weather was still too cold spring. The weather was still too cold and un ettled to put them out, and I had about given them up for lost, when I concluded to try an experiment. I thought the reason for their getting so uneasy was because they were breeding. uneasy was because they were breeding, and as I knew bees consumed large quantities of water when breeding, I concluded to try and make them take water in the cellar. I made holes through my chaff mats and inserted bottles of water with cotton cloth tied over t e nose, letting the bottle come close down to the cluster of bees. The effect was almost magical; they became effect was almost magical; they became perfectly quiet and remained so until taken out of the cellar. These colonies and a large amount of brood and were hatching bees quite rapidly when taken out in the spring. The next winter I determined to experiment a little further with water. I prepared half of my bees so that I could give them water in bottles and about the first of Exhaust bottles, and about the first of February I commenced to give it to them, and con-I commenced to give it to them, and continued to do so until spring. As they were so very quiet. I thought I would see what they would do if their water was taken away from them. Accordingly, I selected one of the colonies that had taken the most water, and took the bottle away from them. They at once manifested their disapproval by making an unrow and boiling out of the bias.

result:
When taken out in the spring, I found

plenty of hatching bees and from two to four frames of brood, while the others had but very little sealed brood, and some none at all. Last winter 1 gave water to all my bees, which enabled me to keep them in the cellar perfectly quiet until all danger from spring dwindling was past. I never saw a lot of bees in as good condition the first of May—strong in numbers, and with plenty of batching brood.

May—strong in numbers, and with plenty of hatching brood.

Doubtless, many will think that it is too much trouble to give their bees water, and I think myself that it is quiet a chore, but it is these small chores that makes bee-keeping a success.

that makes bee-keeping a success.
It takes a man of good judgment and a
keen insight into the habits and requirements of our little pets to make a
good bee-keeper. I think bees need a
great deal of attention and care during
the winter, especially towards spring,
when the weather begins to get warmer.
Coleraine, Mass., Jan. 25, 1881.

Away Down East.—I had 30 colonies of bees last fall in pretty good condition, which I packed for winter. They are in the Quinby standing and Eclectic hanging frame hives, packed with rye, oats and buckwheat chaff—some rye, outs and buckwheat chair—some put in loose and some in cushions. My bees have not had a flight since about the middle of November last, but ap-pear to be all right. Some hives are pear to be all right. Some fives are nearly covered with snow. Besides the 30 on the summer stands, I have II nuclei in the cellar, with 2 and 3 frames each, strong in bees and honey for the number of frames. There are 2 and 3 colonies in one hive, with thin division boards between. They are all right so far. I will report next spring what success I have in wintering them.

ROBERT DOWNS.

Naugatuck, Conn., Jan. 28, 1881

Struck by Lightning.—A few years ago I had my bees placed in rows in round gums; lightning struck 2 of the gums, bursting a good-sized piece out of one, and quite a sliver out of the other. I thought that every bee in the hives was killed; in a few hours they came crawling out of the hives. It looked as though all the bees had clustered on the outside, and they would not fly for three days unless something came near them. It made them the worst bees to sting I ever saw. In one of them I hived a swarm 13 years ago of them I hived a swarm 13 years ago last June. It still remains a prosperous colony. In 10 years it has only swarmed twice, and has wintered on the summer stand. I keep it to see how long a set of combs will last, or the colony die. A few years ago a man named Hastings came into this neighborhood, who said that a set of combs would last 16 years. Mr. Hastings died at Capilela, Lowe 2. Mr. Hastings died at Carlisle, Iowa, 2 years ago.

HIBERT CLARK. Palmyra, Iowa, Dec. 6, 1880.

Bees Uneasy. - Since I wrote you last. Bees Uneasy.—Since I wrote you last, I notice that some of my bees appear to be troubled with dysentery. Those affected, are all young natural swarms which issued in the latter part of July and in August. They had not stores enough to winter on, hence were fed from October 1st until the 15th, coffee A sugar syrup, appends to generate these A sugar syrup, enough to carry them through, I have built an extra No. 1 bee-house for them, with double walls, filled with chaff 12 inches thick; but the house is left open towards the east. Within this chaff-house I have packed my bees in chaff, leaving an opening for the bees as recommended by Prof. were so very quiet. I thought I would see what they would do if their water was taken away from them. Accordingly, I selected one of the colonies that had taken the most water, and took the bottle away from them. They at once manifested their disapproval by making an uproar and boiling out of the hive into the portico. I put back the bottle of water, and they immediately quieted down and remained so. Now for the result: result:

When taken out in the spring. I found any), enlarge the entrance, and thus inthat the colonies I gave water had duce them to take a flight; or would

were carefully moved into their winter-The entrance tubes are proquarters. The entrance times are pro-tected against mice, by wire-cloth, but space is left for the bees to come out. What can I do to bring them relief?
WM. STOLLEY.

Grand Island, Neb.

lBetter let them alone till safe for them to fly; undoubtedly the long confinement, and the feed given them having granulated, has caused the symptoms you complain of; or, may be, they have commenced breeding pretty extensively, which frequently causes unusual activity among the bees, and a necessity for voiding their feces follows activity.—Ep.]

Heavy Rain-Fall.—Enclosed find state-Heavy Rain-Fall.—Enclosed and statement of the rain-fall at Vicksburg for the season, from January to November, 1880, which will about tally with our locality. You will see what chances a bee-keeper had. O. W. Blanton. Greenville, Miss.

The unprecedented rain-fall of this season will long be remembered as the most calamitous that has ever visited most calamitous that has ever visited this portion of the great cotton belt. To the courtesy of Mr. Guthrie, the officer in charge of the weather and signal station in this city, we are indebted for the following valuable and authentic figures, showing the aggregate amount of water, measured in inches and hundredths, which has fallen from the clouds during the eleven months of the year 1880 which have now passed away:

Jun	uary	٠	 				 				1.85	inch	
Posts	ruat	· V	 					,			4.00	, ,	
Mar	ch.,	٠.	 		 				i		11 2 :	٠.	
ADI	il		 				 				9.09	٠.	
May												6.6	
											6.36	h 4	
											4.89	6.6	
											5.67	6.6	
Sepi												6.6	
											5.75	4.4	
											14.15		

Total.....90.09 inches

This makes the enormous aggregate of seven feet and six inches of rain in the space of eleven months; and when it is remembered that the average of the rain-fall in this latitude, taking a series of years by decades does not exceed of years by decades does not exceed fifty-five or sixty inches annually, the immense down-pour of water for the present year is still more apparent."— Vicksburg Commercial.

A New Subscriber.—I am well pleased with the Weekly Bee Journal. My bees had a fly to-day, and are all alive and doing well. Owing to the sever winter, I have my bees packed on their summer stands with hay on the north and west. I have packed them for the last 4 years in that way, and have had good success. David Hohenshell.

Collins III. Jan. 31 1881 ood success. David Hoe Collins, Ill., Jan. 31, 1881.

Temperature in Cellars.—Bees here are wintering very poorly. Many of them are dying in this section and east them are dying in this section and east of here, generally, where they are kept out-doors without much protection. Our bees in cellars are all right. We control the temperature which cannot be done so well out of doors.

3. V. Caldwell.

Camargo, Ill., Jan. 22, 1881.

Doing Well.-I like your Weekly very much and when my 6 months are up intend to renew. Bees all packed in chaff tend to renew. Bees all packed in chaff and every one (21 colonies) answered to and every one (2) colonles) answeren to roll call yesterday. Have not had but one fly since 2d of Nov., and that on Dec. 13. With the many others I wish you a prosperous New Year.

J. W. Keeran.

Bloomington, Ills., Jan. 17, 1881.

Kentucky Notes .- I have been itching to write you congratulatory upon the shape of your new Weekly Brie Journ-NAL. As the ladies say, "it is just too nice," I wanted to get more data from our bee-keepers, which is not over-encouraging, for about two-fifths are dead and the balance to hear from on the 15th of April. Cause—last year was the poorest honey season in the memory of the voldest inhabitant," and it being the second consecutive poor season, the second consecutive poor season, many did not recuperate from the previous year, and this winter, the hardest in the memory of the aforesaid, and lack of interest, from loss of same (as 25 per cent.), all combined, left the few poor bees illy prepared to come out with flying colors. My own apiary (20 colonies) is in excellent condition, plenty of storms and strong large alaction. stores and strong, large clusters. Tex-amined them to-day and am much pleased, they are having a line flight to-day. In my next I will give my ex-perience in wintering, if it should not trespass too much.

W. VAN ANTWERP, M. D.

Mt. Sterling, Ky., Jan. 30, 1881.

Fertilizing Cage. -- I hope you will give M. B., of Fincastle, Ind., a hearty welcome and encouragement on the subject of tertiliza ion in confinement. I ask this of you, because I know you have this of you, because I know you have very little faith in its accomplishment, I wish you had given the full name, for I wish you had given the full name, for it is hard to wait for his arrangement. I want to get ready for another summor's practice, if there are any bees left after this cold weather. Give all the cream in the Weekly, no matter where found. With it and a successful fertilization cage, and plaster of Paris foundation mould, and a live bee-man, success nust be had. cess must be had.

Louis Hofstatter.

Louisville, Ky., Dec. 31, 1880.

f We must confess to considerable incredulity regarding successful fertilization in confinement, to the extent to make it practicable, although no one would buil the successful solution of the problem with more gratification. We have no doubt "M B" will give full particulars of the modus operandi in the columns of the BEE JOURNAL at the proper time.—Ed.]

In the Cellar.—I have received the first number of the Weekly. It is nice to have it weekly, but I fear it will get destroyed, or tornand soiled. We saved from robbing and starving \$4 colonies, from which we have \$19 in the cellar and 6 out-doors. We have taken off about a ton of surplus, mostly basswood, and about half a ton on hand. Bees can be wintered almost anywhere some and about half a ton on hind. Bees can be wintered almost anywhere some-times, and sometimes not anywhere. We have always wintered in the cellar, and have never lost any that were in condition to winter when put in. Three of us put away 100 in 3 hours, and take them out in the same time. The bee cellar is partitioned from the family cellar by building-paper, made perfectly dark. The hives are piled in rows 7 high, like cord-wood, with the front entrance onen and no other workletic. trance open, and no other ventilation. We keep the outside door open most of the nights, which keeps the air pure; the dead bees are scraped out of the hives and cleaned out of the cellar. We put them in before very cold weather, and keep them in till spring. I am satisfied that money paid for the JOURNAL is the best investment that can be made. is the best investment that can be made of \$2, if a man has 5 colonies of bees or more. We used about 100 lbs, of foundation last season, made on Olm's machine, and have yet to see any that I think equals it; at any rate, it is all we want. The cards of comb are as true as a board, and the bees accept it inmediately.

Nashua, Iowa, Dec. 27, 1880. Nashua, Iowa, Dec. 27, 1880.

On Summer Stands.—I have taken the BEE JOURNAL since 1871, and do not like to do without it. I have 106 colonies of bees, all in good condition, on their summer stands, which I think is the best place for them, after trying va-

rious ways of wintering.
P. D. Jones.

#### THOMAS C. NEWMAN,

EDITOR AND PROPRIETOR.

CHICAGO, ILL., FEB. 9, 1881.

#### Accumulating Disasters.

From every point of the compass.north, south, east and west—come tales of losses and disaster in wintering. The poor honey yield of last season, combined with the early advent of cold weather, and its long continuance without even a slight intermission to admit of a "fly," is telling with fearful mortality among the poor bees: and many bee-keepers who met with discouragement in the spring, and with whom there was no encouraging yield during summer or fall, and now have lost even the few they had left, may well be pardoned for becoming "blue" over the prospect in future. Many fed their bees enough to last till the traditional "January thaw" took place; but January has come and gone, and no moderation of the weather has taken place of suflicient length to give the bees a good flight, or allow of feeding. In this latiitude cold weather set in during October, and caught most of the bees not yet properly prepared for even an ordinary winter, and too many are in that condition yet. Ordinarily, there is plenty of good weather in November for teeding and packing bees, or putting them in the cellar, but this has been an exception. Then, in January-certainly by the 20th, generally sooner—a mild spell and thaw of several days' duration has occurred, when bees could be fed and looked after; but this winter one eold spell has but partially moderated to be succeeded by even colder weather: snowstorms have abated only to be followed by stronger ones; western winds have changed only to "nor'-westers" and northers; our balmy breezes have been transformed into "blizzards," and the gales have assumed the proportions of hurricanes and tornadoes.

Not alone in this latitude have these extremes occurred. From Canada to Texas, Minnesota to Florida, Maryland to California-all over the Continentcome reports of weather without precedent. One correspondent no sooner complains of the weather at 15° below zero in his locality, than another puts him to shame by writing of the 40below in another location. Railroad trains have been irregular as a rulenot as the exception. From England and the Continent we learn the epidemic of extremes also prevails. Bee-keepers there, as here, have become quite familiar with the oft-repeated line from Shakspeare-

Now is the winter of our discontent"

but the remainder of the quotation is ignored, for nothing has tended to make it "glorious." With many, already, the uncertainty of wintering has been reto put an end to their doubts and misgivings.

gain," but perhaps in this case the gain he arrived hours behind schedule time.

will be principally in bitter experience. Opinion has been greatly divided as to the best method of wintering-whether on the summer stands or in the cellars: whether with chaff-packed hives, airwalls, over-absorbents, lower ventilation, or no ventilation at all. New theories will be promulgated, and old ones abandoned or confirmed, while the "I told you so" class will be more persistent; than ever, should their theories and claims be substantiated by success. Should the bees all be dead in an apiary, there is still the consolation of having the hives and combs left, and the total loss is but partial, after all. Most of the sufferers will not be discouraged, but with hope of better success in future will try again, and with the experience of the past to guide them in the work to come, must succeed in overeoming all difficulties, and their labors will be crowned with victory.

It will be interesting to scan our colums when the result is fully known, and compare the various methods of wintering with the different degrees of success. Of course, very many will come through the winter with but trifling loss, but the majority of beekeepers will, in years to come, recall the winter of 1880 SI as the season of disaster to bees. The BEE JOURNAL will possess a peculiar interest to all, affording an opportunity to avoid the errors gestions from its many contributors for guidance in the future.

prediction of Dr. Brown, of Georgia: Without consulting Vennor, or any other of the prophets, 1 prophesy that the year 1881 will most abundantly reward the industrious bee-keeper."

#### . . . . . Colchian Honey.

As bearing upon the frequent allusions to poisonous honey, Mr. II, G. Colwell, of Columbus, O., quotes from ancient history the following in reference to the famous Colchian honey. We have frequently seen allusions to this honey and its singular effects, but have never been favored with a satisfactory solution of the problem he propounds. Perhaps some of our learned complaints against several prominent contributors can give the information grocers of whom I had bought the speccontributors can give the information desired.

the famous During the retreat of Ten Thousand from Asia Minor to their homes in Greece (B. C. 401), they passed through the territory of the Colchians. The country literally flowed with milk and honey, the soldiers were well received, and refreshed themselves after the innumerable hardships they had undergone, by a repose of thirty days. undergone, by a repose of thirty Gays. They partook of the Colchian honey, and it produced a singular effect upon the Greeks. It was very well flavored and myiting to the palate, and when eaten in small quantities caused a species of intoxication; but those whose caused a gluttonous appetites lead them into excesses, were seized with violent fits of vomiting and diarrhea and sometimes thrown into a state resembling madness.

Query:-Why did the ancient Colchian honey cause the above disorders?

The editor of the BEE JOURNAL is now absent. He left Chicago on the lieved by the certainty of loss, and 31st ult., to attend the Northeastern others await with anxiety the slowly Convention, at Utica, N. Y., on the 2d, approaching months of Marchand April 3d and 4th inst., and will return via Ohio to attend the Convention at Audover, O., on the 8th and 9th inst. He It has been truly said, "there can be left in a snowstorm, which prevailed nogreat loss without some compensating aduring the whole trip to Utica, where

#### Food Adulterations.

It is gratifying to contemplate the subject of food adulterations, in all parts of the country. Not only are the masses of the people, individually, falling into line, and closing up the ranks of the great army of opposition to fraud and swindling, but societies, corporations and communities are becoming awakened at last, and the good work is beginning to assume shape and dimensions that will eventually demand active recognition in the halls of Congress. Every mail brings letters encouraging us in the good work we have commenced of an unrelenting warfare upon this daugerous and enormous system of thieving. Meantime, let the agitation be continued, and everywhere denounce the sale of any article, whether in quantities great or small, by any other name than its proper one. We expect shortly to be able to present our readers with a perfected bill embodying our views, and providing for a general remedy to all classes of honest producers. The matter is now under consideration by an eminent jurist and legislator of Iowa, and we have no doubt it will meet the long-felt wants of the public, and give our readers a basis or standpoint upon which to work.

We are satisfied a general law will be of the past, and containing timely sug-the only redress, and our former belief regarding the futility of special legislation by State bodies, is strengthened by After all, it is refreshing to read the scores of letters and congratulations. In confirmation, we give the following letter written by Prof. J. Hasbrouck. to the Bec-Keepers' Magazine, and published in the February number of that paper. As it explains itself, we will make no further comment at this time:

> Probably many of your readers will be interested to know the fate of the effort to enforce the law passed by the Legislature of New Jersey in the win-ter of 1878-79 against the sale of adul-terated honey. In the early fall 1 terated honey. In the early fall I gathered 15 or 20 bottles of what is sold in the groceries of Jersey City as "choice honey," and, upon analysis, finding honey, and, upon analysis, finding them to consist almost entirely of glucose syrup, flavored with a little honey or wintergreen oil, I went before the Grand Jury of the December term of Court in Hudson County, and entered imens. I am sorry to say that grand inquest failed to inc Their reasons I could judge from I could judge from the questions asked me.

We are sorry to learn of the misfortunes of Mr. A. F. Moon, and feel confident our readers will all sympathize with him. His has indeed been a trying time. The following is an extract from a private letter recently received:

The past has been a most unfortunate The past has been a most unfortunate season with me. I have received no honey, and had no queens or bees to sell, and have not been able to transact any business, on account of my lameness, which ended in the loss of my limb. In fact, I was compelled to go on crutches all the season. I am somewhat hatter all the season. I am somewhat bette now, but have not been to our postoffic I am somewhat better now, but have not been to our postence since the 11th of last May, which is only 2 blocks from the. This, you know, is hard for a man accustomed to walking and stirring around. I live in hopes that this year will be a good one for both bees and honey. We had a few cold days in December, but the weather is the loss are flying and cold days in Occember, but the weather is warm now; the bees are flying, and some are carrying in bee-bread. By the way, the Weekly came in to-day's mail, which just fills the bill; it is just what all bee-keepers want—a Weekly BEE JOURNAL. Long may it live, with success to its editor.

A. F. Moon.

Rome, Ga., Jan. 16, 1881.

#### Artificial Comb Honey.

The Weekly BEE JOURNAL made its general interest being awakened on the appearance, and I also add my testimony general interest being awakened on the appearance, and I also add my testimony general interest being awakened on the appearance, and I also add my testimony general interest being awakened on the appearance, and I also add my testimony general interest being awakened on the appearance, and I also add my testimony general interest being awakened on the appearance, and I also add my testimony general interest being awakened on the appearance, and I also add my testimony general interest being awakened on the appearance, and I also add my testimony general interest being awakened on the appearance, and I also add my testimony general interest being awakened on the appearance, and I also add my testimony general interest being awakened on the appearance, and I also add my testimony general interest being awakened on the appearance. doubt receive all the support necessary to its successful retention as a Weekly.

The following appeared in the Toronto  $Glob\epsilon$  yesterday and surprised me not a little, and as I could not believe a word of it. I wrote to the editor and contradicted it, for could there really be such an institution in existence without your think of leaving the bee-keeping fra-ternity in such blissful ignorance. Well here it is:

"Some unsophisticated purchasers of honey imagine that by buying honey in the comb they are sure of getting an madulterated article. A great mistake. There is an establishment in Boston where artificial combs-not foundation merely, but combs—are made in such perfection that it would require an exmade in such Paraffine, not d. When the pert to detect the fraud. way is the material used. combs are made they are filled with imitation honey made from glucose, worth 3 or 4 cents per lb., and flavored to taste. A hot iron is then passed over, the cells and the 'comb honey ready for sale.

What use will there be for your much cherished coming bee. Apis Americana, in the face of such comb honey—makig by automatic process in your midst. I hope for a cheerful rejoinder from your pen on the above.

In your number for Jan. 19, your correspondents. Greiner Bros., refer your readers in one of their paragraphs to page 355 (1879), where he has recourse to the what he calls "shaking off proto the what he cans "snawing on pre-cess," but I cannot find anything in that JOURNAL on that point. Will be please explain? I am much interested to know how done, &c. I have gone through all the same processes to prevent swarming with the same results as he has, and not only removed every queen-cell, but at the same time took all the honey away from 28 colonies in 1879, and every one swarmed within 2 days after the operation. Colonies that I ran for the extractor, I never had one yet to swarm. I have had them preparing queen-cells and capping it, and yet not swarm, and this all in a good flow of honey, and its preparation not being a supersedure either, for the cells had all disappeared inside a week, and no honey removed from the hive during the time. Of course the colony had all the combs they could cover. C. WURSTER. Kleinburg, Ont., Jan. 25, 1881.

Mr. Warster was right in denying the article in the Toronto Globe. We frequently hear, from the unsophisticated, doubts as to the purity of comb honey, and it is not to be wondered at, when almost every delicacy, and, in fact, nearly every necessary in the food line. is adulterated; but the manufacture of artificial comb has never yet been accomplished. Neither do we believe that bees have been seduced into making combs from paraffine wax. So that all may rest assured of the purity of the wax composing the combs in which the bees store their honey. As to inducing bees to store glucose for honey, it is a matter of doubt whether it can be done with sufficient profit to tempt the enpidity of any dishonestly-disposed bee-keeper; and it would require a very skillful bee-keeper to succeed in having it stored and capped over. Again, the feasibility of capping or sealing honey with a hot iron-well, the writer of the paragraph referred to might put in a few weeks very industriously experimenting in that line, and, after repeated failures, he would conclude that the success of the frand existed only in his inventive imagination. Of course, we make no allusion to the difficult task of. depositing the glucose in the cells, which will be tound a work requiring

considerable time, a steady nerve, and more patience than the ordinary price of comb honey will repay.

On referring to page 355, 1879, we find no correspondence from Mr. Doolittle. to which Messrs. Greiner Brothers refer in the Weekly Bee Journal of the 19th ult., and we leave to them to explain the process to which they refer, as some mistake has occurred in the citation.

#### Flat-Bottom Foundation.

The following letter from Mr. O. J. Hetherington, was read before the Michigan State Bee-keepers' Convention, held at Lansing, Dec. 8, 1880. The minutes were not received at this office until the 26th ult., so we could not puband them till now. As much interest has been manifested in the subject of using full-size sheets of foundation in . the surplus boxes, and as this letter bears principally upon that subject, we give it a place here in extenso. The letter bears date East Saginaw, Mich., Dec. S. 1880:

I was in hopes to have been with you to-day, but as my bees are not in the cellar yet, I do not feel as if I could spend the time, until I get them out of the cold; and it is bearing down so much more heavy than usual, that I feel library which we start the cold; feel like working night and day till I get them in.

I wanted very much to be at the Convention this year, as I have several points I would like to present, as to my experience this summer with flat-bot-tom foundation of full size in sections. I have used it full sized in all my sec-Thave used it time sized in an my sections but about 200, that I had of last year's, that had triangular starters in, about 3 inches on a side. Using both I could see the difference.

could see the difference.

The bees work the flat-bottom as near the shape it ought to be as possible, which compels them to thin it down, so it is about as thin as they make the comb themselves. This year was a poor season, but I think I secured twice as much comb honey as I should if I had not used the foundation full size in the sections. Perhaps in a good season if not used the foundation fun size in the sections. Perhaps in a good season it would not make quite as much difference; but from my experience, the past summer, I know they will make very

summer, I know they will make very much more honey.

At the time the bees commenced to gather honey from boneset, they obtained it very fast for two days (that happened to be clear and pleasant), and during those two days the bees drew out the foundation the full length of the cells and filled it with honey; then we had nearly a weak of wat rainy weather. so the bees could hardly do any thing, and they did not seem to do much of any thing to the honey in the sections. My theory is, that the weather was so wet and damp that the bees were unable to evaporate the honey so they could seal it up, for as soon as the weather came off dry and pleasant, they had every-thing sealed up in 24 hours. Also the Italians will commence work

Also the Italians will commence work in the sections as soon as the blacks, and they both will commence much sooner than when only starters are used. I would not recommend anything but the thin flat-bottomed foundation, as that is the only kind the bees will work the base of the cells thin enough to

The Prospect for honey in California is promising. Mr. S. D. Barber, in the Semi-Tropic Californian, says: "We find many of our hives with three and four sheets of brood well tilled. from eggs to the hatching bee, on January 4th, 1881. The prospect here north of the city indicates an early and prosperous year for business. Be ready. Do your work in time. A day lost with bees is forever lost. What is termed luck with bees is only another name for careful and skillful management.

#### GLEANINGS.

Cyprian Bees.—The following is an extract from Mr. Frank Benton's last letter, dated at Larnaca, Cyprus, Dec. 14, 1880. We devote so much space to it as it is a subject on which information is eagerly sought, and but little experience has yet been had in this

Under all conditions and at all times of the day, even from daylight until 9 o'clock at night, I have handled Cyprian bees, without snoke, and with no beeveil nor even a hat on my head. Bareheaded, bare-handed, with low slippers on my feet, no coat nor vest on, my shirt on my rect, no coar nor vest on, my sufficient low in the neck, and all my garments thin, I have worked hour after hour among the Cyprians just as fast as I could make my limbs and body move, transferring colonies, dividing swarms into nuclei, and putting up queens for shipment, all the while shakig and brushing the bees about just as though they were so many Italians, and though they were so many Italians, and a big basswood harvest was on hand. I say shaking them, for they can be shaken from the combs quite as easily as can black bees, and brashing them is a dangerous experiment unless they are well filled with honey. Now, it must be remembered that all this was done at a time when we have we coming in and time when no honey was coming in, and when feeding had not been kept up regularly, the colonies that had not been fed and those that had having been opened indiscriminately; the handling was often at the most unseasonable was often at the most unseasonable hours of the day; and, lastly, there were often many visitors present; yet I was rarely stung, and I recollect but one instance in which a visitor was stung.

stance in which a visitor was stung.

The only points I observed carefully were the following: I opened the hives with extreme caution; the quilt was removed slowly, and the bees left to themselves for a moment before I touched the frames; then the first frame was very carefully removed, after which no further especial caution was needed, except that there must be no jarring of frames, either in removing them, in handling, or in replacing them. Any one would be likely to say. These things are all very good to observe with any race of bees; but will they prevent Cyprians from stinging, when their observance in handling blacks and Italians ospirans in handling blacks and Italians under the conditions you mention, would avail little as far as keeping these races under subjection is concerned?" It seemed to answer with me, and I discovered that the Cyprians were very susceptible regarding the sudden admission of light into the brood apartment, and they resent in the strongest manner any jarring of the hive or combs. I think they are far more likely to be aroused by either of these things than aroused by either of these things than are the Italians or blacks, and are not as easily subdued with smoke, or, in fact, at all. They will follow the beekeeper with great pertinacity as he leaves the hive, going a long distance, and even through several doors, for a chance to sting. When a hive is once thoroughly aroused, the better plan seems to be to close it and leave it for seems to be to close it and leave it for an hour or more.

They meddle with passers by who do ot touch them, less, even, than the alians. The above would likely lead Italians. to incorrect inferences should I close this subject without stating the conclu-sion which the season's work among the bees of Cyprus has caused me to form regarding the relative rapidity with which Cyprian and Italian bees can be handled; hence I state here that I fully believe I can handle the Cyprians with -half greater rapidity than I can the Italians; that is, with proper management, a given operation in manipulating bees can be performed with three Cyprian colonies while the same operation is being done with two Italians....

ing into account of course, the age of the bees and the amount of food they were likely to have in their bodies. The true Cyprian is a yellower bee than the Ital-ian; indeed, I think the average Cyprian is yellower than the brightest Italian. I refer to the worker bee alone. Its body is more hairy, and the abdomen more slender than will be found among more slender than will be found among Italians. When filled with honey, the worker shows three yellow bands, as does the Italian. Mr. Cori, of Bohemia, who first described these bees, and procured the first colony from Cyprus, stated the worker bee has only two yellow segments, but he surely failed to count the end segment, next to the thorax, the end segment, next to the thorax, without which the Italians would have but two yellow bands. The fourth yellow band, as with the Italians, is some The fourth veltimes seen, but a more distinctive mark times seen, but a more distinctive mark is that the segments back of the yellow bands are so tipped with whitish hairs as to give the abdomen of the Cyprian a very ringed appearance. The two most distinguishing marks are, however, the following: The pure Cyprian is yellow on the under side of the abdomen, from the tip nearly forward to the thorax: and, second, the shield on the back of the thorax between the wings is very prominent and plainly yellow is very prominent and plainly yellow. On account of its shape, I call this the or account of its shape, I can this the crescent, and it shows that its bearers are from the Turkish empire, or descended from those who did come from this far eastern land. The Cyprian drones are in general much more mottled with yellow than the Italians; and though they are not uniform, many are of a very brilliant golden hue.

I find the Cyprians active, strong-winged, sturdy defenders of their hives, tighting against fearful odds to preserve an existence, exceedingly keen-scented. so that no drop of sweet escapes their notice under conditions which would notice under conditions which would conceal it from other races of bees. They are very prolific, and rear brood late in the season. We have had frost here, yet to-day I find brood in all stages in hives of Cyprians. One other quality of great importance is noticeable: A street wind is keeded but the first conditions and the season of th of great importance is noticeable: A strong wind is heeded by the Cyprians, and, upon its appreach, they gather in their hives to avoid it; or, if the day open windy, they do not venture forth. Those who have them in America will note this, and that they will not dwindle as the Italians do during the coming spring. Still another point in their fa-vor is, that they can be shaken from the combs very much as though they were blacks; but if left to themselves do not run off, having in this particular the same disposition as the Italians, name-ly, they spread evenly over the combs and remain quiet when the latter are handled.

Preventive of Robbing. -- Mr. Val. D. Urich gives the following as his method of stopping robbing:

I will give you my way of curing 10b-bers, which always proves satisfactory to me whenever I try it. When the robbing commences, and the colony to be robbed does not fight the robbers away, I close up the entrance pretty small; then I take a small piece of broom corn (which I like best) or quite a little whip, and stick it in at the broom corn (which I like best) or quite a little whip, and stick it in at the entrance, and shake it pretty often. That makes them so cross that they will mount a robber before he is halfway down to get in; but put on a veil, or they will will take you for a robber. If they have full sway of a colony before I find it out, I close it up entirely till next meaning when I make them denext merning, when I make them de-fenders before the robbers are up. Sometimes it must be done pretty often before they stop it.

Paper Honey Comb. - F. Della Torre makes the following suggestions:

Will you induce Mr. Gray to make a machine that will turn out artificial honey comb complete—made from shellac tissue paper, and in a way similar to that described in Quinby's "New Bec-Keeping," which uses tin? I am sure it would be a success, for I have used a small source of horner's west earls in The bees of Cyprus are very uniform it would be a success, for I have used a will most abundan surprisingly so, I think. We obtained small square of hornet's nest comb. in trious bee-keeper.

colonies at many points distant from each other, and saw bees in many places where no purchases could be made, but all presented the same appearance, takcess. After "uncapping "it to \( \frac{1}{2} \) in, depth of cell, I just dipped the rough edges in melted wax, to make the bees think they were composed of that material all the way to the bottom. The shellar would serve to hold the strips founting in the great way to strips the strips of the strip of the st together in this case, as the solder does in the other. These little bottomless cells could then be stuck to a flat sheet of shellac paper (one set on either side). then by touching the edges to melted wax your comb is finished.

> Dysentery.—The following is given as a remedy for dysentery :

My bees had the dysentery the worst lever saw. I went into winter-quarters with 13 colonies, and before January I had lost 6, and 7 had died on account of the cold weather and dysentery, so I had to practice something to keep up my 6 colonies. I put them in the cellar, took out their stores, and gave them a frame of candy, and the same time I fed them syrup in which I put a few drops of mint. Both were made of granulated sugar. I also gave them all the ventilation I could to get out the foul air. In about a week they were all My bees had the dysentery the worst foul air. In about a week they were all well, and their excrements are now dry, and the bees are all well up to date.

#### BEE-KEEPERS' MAGAZINE.

Apis Dorsata and Apis Zonata.-We make the following extract from a letter from Mrs. Frank Benton, dated at Larnaca, Cyprus, Dec. 10, 1880:

You doubtless know of the many hindrances my husband has had to con-tend with during his stay upon this Island, also of his different attacks of sickness—ophthalmia and tropical fever. Now that cooler weather has come his

Now that cooler weather has come his former vigor is gradually returning, and no doubt he will soon write you again.

Just at present he is very busy making preparations for a journey to India and the East India Islands, his object is to procure the long talked of bees, Apis Dorsata and Apis Zonata; also any other races of excellence which he may find there. He will also look up some other points, such as gathering seeds of important honey plants, and of differingortant honey plants, and of differingortant honey plants, and of differingortant honey plants, and other points, such as gathering seeds of important honey plants, and of differ-ent grains that may be profitably culti-vated in our native land. He will take with him thirty or thirty-five colonies of Cyprian and Syrian bees, most of which will be taken to Java.

Should success attend him, which we sincerely hope will be the case, the new

sincerely hope will be the case, the new bees will be sent directly to America.

His proposed route from here to Batavia, Island of Java, is as follows: Beyrout, Jaffa, (Syria); Port Said, (Egypt); through the Suez Canal and Suez; then down the Red Sea to Aden, (Arabia); across the Arabian sea to Bombay, in Hindoostan; thence to Colombo, Island of Ceylon; then to Singapore, Farther India; probably, also, to Timor, to the Celebes and the Phillipine Islands.

He will leave here the 21st of December, and hopes to return to Cyprus early

ber, and hopes to return to Cyprus early in the spring, in order to continue rearing and shipping Cyprian queens.

California Prospects.—A writer at North Temescal, gives the following encouraging report:

At this time (Dec. 20) the prospects for an abundant honey crop were never better. Frosts were a month earlier than usual-rain six weeks behind time. now the earth is saturated with water, grass is growing with a will and it is almost fit for grazing. From present admost ht for grazing. From present indications we are going to have a mild winter, with plenty of rain withal. If this should happen to be the case, and March north winds do not visit the fertile plains and valleys of this coast, and should the atmosphere be charged with that degree of humidity which is so conducive to the secretion of nectar, then the honey yield of this State will be enormous.

Dr. J. P H. Brown makes the following encouraging prophecy: "Without consulting Vennor, or any other of the prophets. I prophesy that the year 1881 will most abundantly reward the indus-

#### Michigan State Convention.

Met in Pioneer Hall, State Capitol, Lansing, pursuant to call, Dec. 8, at 41

So little time remaining before noon -Prof. Cook moved that the meeting spend the morning hour in conference. and said L. B. Baker's bees were in the open air without chaft or other protection, and the Professor would ask what the different members would do with them, seeing that they had now been out so long in the cold?

out so long in the cold?

C. B. Link stated that dampness was the principal cause of loss.

L. B. Baker said he intended to take them in but thought best to let them alone till warm weather, as they seemed to be all right so far.

The Secretary was asked what he

Secretary was asked what he The Secretary was asked what he would do with them, and said that if he had a good cellar as Dr. Baker's, he would take them in carefully and slant the hives so the water would run out;

the hives so the water would run out; then partially open the top so the hives would dry out.

Acting Pres. Ashley, of Ypsilanti, stated that if the senson was as last be would leave them out; but as it now seems, he would favor the opinion of Mr. Bingham, and take them in.

B. A. Salisbury, of Battle Creek, favoration is being a simple of the particular contents.

ored wintering in boxes filled with chaff

3 inches deep all around, and preferred it to cellar wintering.

Mr. Cole, of Livingston, thought it a bad time to move bees; he moved some into the cellar once when so caught, and let begin to be some into the cellar once when so caught. lost heavily; he said 90 per cent, of the bees designed to be protected were now in the open air unprotected having been caught by the early winter.

Mr. Smith asked why bees did not winter as well in frame as box hives,

winter as well in traine as now lives, without protection.

Prof. Cook said Mr. Hurlburt lost his regardless of the old box hives he used; he did not think the hive was the cause. he did not think the hive was the cause. Neither was he fully satisfied that chaff hives would entirely obviate the dangers of ont-door wintering. We need another 1873 winter to test them. Our few past winters have been such that we could not safely predict what a severe winter would do. If Dr. Baker should move his bees into his cellar and then warm it slowly there would be but then warm it slowly there would be but liffle danger.

nttle danger.

Prof. Cook suggested that hereafter our meetings be held the first Thursday after the first Thursday in December, and that time was unanimously chosen; and Battle Creek the next place of

meeting.
1 P.M.—Vice Pres. Ashley, of Ypsi-

1 P.M.—Vice Pres. Assurey, of 1 psi-lanti, called the meeting to order. Prof. Cook said that black bees were more prompt in entering surplus boxes, but did not regard that of importance. as by the present means we had no dif-ficulty in getting Italian bees to start ficulty in getting. Italian bees to start combs in the lower part of the hive after which they could be raised, and the Italians would go on with the work without loss of time. Black bees are said to dwindle less in spring, if so, it was an advantage. Italian bees thy was an advantage. Transh boes by early, and do not run on the combs. The Students at the College say the Italians fly earlier and later than the blacks. Italians are said to be cross, but I know pure Italians are more gentle and better natured. I have Halv or the and better natured. I have Holy or Palestine bees, and they are the only bees I have ever seen that would dupli-eate themselves. They also breed later, cate themselves. They also breed later, and I did not have any queens that laid so fast. I favor dark Italian bees while others profer the light. The Cypran bees must be better. They are left to themselves in Cyprus, and only the fittest have survived. Adam Grimm believed the darker bees to be the best while the Cincinnati Convention allowed it to go out that the light ones were best. were best

were best.

Louis Harper, of Delhi, said be had light-yellow Italians and beheved them best, but had never had dark Italians, nor did he want them; he liked the light-haired bees; they could be held up to view and were beautiful. But he

wanted honey-gatherers, and favored

wanted noney-gatherers, and lawored the lighter Italians.

Prof. Cook said he believed we should get the best bees from importations. I am perfectly willing to go on record in that matter. Nature does her work bet-ter than bee-keepers. The best I have ever seen are those that have been imever seen are those that have been imported. If I had been at Cincinnati I should have protested against the opinion going out that the American-bred training. Italians were best

Mr. Robinson, of Pewamo. I have a few nice bees—but they have cost me \$5 to get them off—that is, changing from light to dark, and I am glad to get rid of them. I now have only dark; a man could not give me yellow Italians.
W. R. Cole, of Belleview. In August I found my Italians on red thistles

and doing well, while my blacks worked on clover, and accomplished very little.

on clover, and accomplished very fittle.

Mr. Harper stated that some advocated black bees, but he believed that
none were to be found pure. All that
we now have are dark-mixed Italians, and the yellow are best. If I had to keep black bees, I should not keep any. L. B. Baker. We have had black bees, and if they were best we have had some-

thing to be proud of.

Mr. Smith said the largest comb honey yield he had ever had were from black bees. I have an imported queen and have bred from her 18 others; she was very dark. They have certainly stored very dark. They have certainly stored no more honey than my light bees. I have an apiary away from home of pure black bees, and they have produced more honey this year than my others. But I always show my light bees to strangers. He said his stinging bees strangers. are his best workers, and he liked them.

Mr. Bingham, of Otsego, stated that e-cultivated dark Italians—but had both yellow and dark, and pure blacks. In the fall always reduced the number of his colonies—sometimes more than half, but never killed a queen whose olony had done well because black, or yellow, or dark—"Pretty is at pretty does."
Mrs. L. B. Baker, of Lansing, who

has kept a strict account, says the dark Italians have proved much the best honey gatherers with her. A resolution honey gatherers with her. A resolution was passed that it was the sense of the Convention that dark Italians were preferable.

Prof. Cook moved that all the essays from abroad be received and the writers thanked for their kindness in sending them. The resolution was unanimously

Mr. Robinson was called for, and said Air. Robinson was called for, and said surplus was what he kept bees for; used the extractor mamly; did not extract from the brood chamber, and never ex-tracted till the honey was ripe and mainly scaled; uses a Bingham & Heth-erington knife and like it best; can do work faster and better with it than any work faster and better with it than any other; sell most of my honey in Pe-wamo; carry 20 to 25 queens through the winter for spring use; can winter them safely on one comb.

Prof. Cook thought the wintering of extra queens a matter of great importance; he had never failed in wintering bees in small hives. They cannot be wintered in chaff hives, but can in the

llar. Mr. Salisbury wintered a small colony on candy and flour and water, and it was the best colony he had the next

Mr. Robinson said getting honey was not all; it had to be kept and the mar-ket waited for; had no trouble in selling all he could get.

Prof. Cook said uncapping took time; as soon—as it was partially capped and thick it could be extracted. Never had

Mr. Cole never let his bees cap than a place as large as his hand before xtracting; never had any sour.
Mi. Robinson had several barrels

spoil, and care was required unless thoroughly ripe.

Mr. Bingham said he believed it un-safe to extract before it was esentially scaled. Believed the honey better and for remaining some time scaled

Prof. Cook said, take off your sections fairly before the people, it would prove as quick as done. All the nice section itself one of the most profitable of honey is made quick and removed at Conventions. T. F. BINGHAN, Sec. once

Mr. Robinson, said, honey would not granulate if kept up to 90 but would if

Mr. Bingham asked how much more extracted honey a colony would yield than section.

Mr. Robinson said he extracted 200 lbs, per colony; but should not expect more than 50 lbs. from the same colony, if in sections.

Mr. Hilbert said 30 colonies gave 3,000

Mr. Hilbert sam or vocants a garden bls. in sections.
Dr. H. B. Baker, Sec. State Board of Health; Dr. J. H. Kelley, of same Board, and Mr. L. B. Baker, were appointed a committee to urge legislation.

ommer a committee to fige registation calculated to prevent the adulteration of honey and other sweets.

Mr. Benham, of Olivet, stated that he had had some experience in comb foundation. He wanted to furnish and had dation. He wanted to furnish and had furnished good material. Had hand-some foundation well drawn out that the queens refused to fill with eggs, and was fearful the wax was impure making from his own wax, with his own machine, had no trouble. Thought a machine, had no trouble. Thought a machine would pay. Foundation was

invaluable.

Mr. Perry said he would not do with-Bees accepted the Dunham ont it.

out R. Bees accepted the Dulham foundation most promptly.

Mr. Robinson preferred Dunham foundation and thought it would soon go ont of use; he was willing to go on record, that it raised too many bees. Mr. Smith liked it, said it made 4 to 6

days saving in tilling a hive with combs.

Mr. Waldo said full frames sagged somewhat, when filled with it. I think it beautiful, and favor its use.

T. F. Bingham had filled his shallow T. F. Bingham had filed his shallow frames and hived full colonies on Dun-ham foundation with the mercury at 96 without any sagging; but had al-ways taken the precaution to place an empty hive under the one containing the foundation, that the bees might have room to distribute themselves so as not take generalized to alustration. to be compelled to cluster on dation while it was being drawn out. Then after a few days removing the empty set. Believed this plan would usually prevent sagging even in Langstroth frame:

Mr. Smith had used wired-foundation and it had worked nicely; saw no objections to the wire; said the flat-bottomed was the thinest he had ever seen.

Waldo stated that in all the apiaries he had visited where foundation was used, he had found more or less

sagging. L. B. Baker said he had used founda tion and had never had any sag, but had never put large swarms on it. Prof. Cook said he believed founda-

tion a success.

Mr. Perry said some used would settle, while some would not.
[A letter was here read from Mr. O. J. Hetherington, which will be found else-

where in our columns — E.D.]

Pres. Ashley and Mr. Robinson were of the opinion that there was a loss of from 6 to 15 per eent, of wax in the process of making wax into foundation.

Mr. Perrythought the loss in working pure yellow wax was merely nominal.

Considerable discussion was brought forward as to the means to be adopted so as to unite all the bee-keepers.

The President said those who attend

must condense and arrange so as to tell just what they wished in a few words.

Mr. Robinson said he did not want to tell all he knew. There were more beekeepers now than he wanted. More honey raised would not increase the

oney raised would not increase the demand or raise the price.

Mr. Perry said the business would regulate itself.

Prof. Cook did not like the Chinese

plan. Parties who formerly talked it, saying we had too many bee-keepers. were now taking another course.

Mr. Robinson said alsike clover had been a favorite with farmers about him, It made good hay, seeded well, produced about 5 lonshels of seed to the acre; if sown with wheat in the fall, it would bloom and yield seed the following season. It will bloom the same season, if sowed early, and seed the first crop. It said, if this Convention could bring the adulteration and foul-brood matters.

President—Chas. A. Pierce, cf Trux-ton.

Vice Presidents—J. L. Gillett, of Cortland; E. II. Knapp, of Fabius; W. L. Coggshall, of West Groton.

Honorary Vice Presidents—G. M. Doolittle, of Borodon; I. L. Scofield, of Chenango Bridge; II. D. Mason, of Fabius; Osear Courtney, of Marathon; R. H. Mellen, of McLean. Mr. Robinson said alsike clover had

[The essays and correspondence read at this Convention have been published in the BEE JOURNAL.—ED.]

#### Cortland Union, N. Y., Convention.

The annual meeting of the Cortland Union, Bee-Keepers' Association was held at Cortland, N. Y., Jan. 4, 1881, and well attended.

The discussion of the day was begun by E. H. Knapp upon "Rearing Italian queens." He related the methods purqueens." He related the methods pursued by hinself and brother. During the last season they had raised upwards of 100 queens, and principally by the practice of "grafting." It consisted essentially in removing the eggs or larva from queen-cells in the earlier stages—the larger cells having previously been all removed—and replacing larva 6 to 12 hours old, taking from worker cells of the colony to be bred from. The bees took cure of them in same manner that they would if undisturbed. The best queens were produced by taking larvæ soon after hatching; thought it the most satisfactory and certain of any method he knew

knew.
The discussion was continued by Pres. Pierce, Messrs. M. C. Bean, E. Cory, J. H. Kennedy and others. The relative merits of this method as compared with others, the length of time after the operation before the cells might be removed, probabilities of their being torn down, the age of larva it was best to take, the effect of increasing the amount of royal jelly in the cell, and other points, were dwelt upon. other points, were dwelt upon.

The discussion of the afternoon ses-

sion was begun upon the subject of foundation in hives and surplus boxes, by W. L. Coggshall. He had used several kinds; had tried that with high eral kinds; had tried that with high side-walls and with none; preferred the former; had used the Dunham and the Olm; had used the flat-bottom with good success in sections; he endorsed fully the article by C. C. Cofinberry, at the Cincinnati Convention; would not advise any bee-keeper to compel bees to make combs when foundation was at present prices. The discussion became interesting and lively upon the subject, and took up the rearing of brood over the wires in wired-foundation in full the wires in wired-foundation in full frames, and hiving bees upon foundation. It was participated in by Pres. Pierce, Messrs. E. Cory, R. H. Mellen, F. W. Smith, J. H. Kennedy, E. H. Knapp, M. H. Fairbanks and M.C.Bean. "Wintering bees" was now introduced by A. G. Chapman. There were as many methods as bee-keepers; he

said the beginner would find the opinions and methods of leading men at variance on the subject; but he thought there might be some factors common to all, obscure though they might appear in some. Dryness he concluded as one. His method he described to be as fol-His method he described to be as follows: He kept 2 colonies in one hive; this was set permanently on a good foundation. It had a lid like a trunk, with hinges on one side; inside, and leaving space for packing, was a box made cheaply of half-inch lumber that would hold 20 Langstroth frames and in the courter harbesed a thin devision would hold 20 Langstroth frames and in the center he placed a thin division board to separate the 2 colonies. They were kept comfortable, and he liked the method. The subject was kept up by Messrs. Smith. Knapp, F. Schermerhorn, Mellen and Pres. Pierce.

The Association listened to the Annual Address of the President, Chas. A. Pierce. He spoke of the encouragement the Association was to all, and the progress it had made in the past year of its organization; it now numbering

organization; it now numbering rly 50 members.

The Convention proceeded to the elec-tion of officers for the ensuing year with

following result: President—Chas. A. Pierce, of Trux-

Secretary-C. M. Bean, of McGraw-

Treasurer-J. W. Cudworth, of Me-

Grawville,
The Chair appointed Messrs, Kennedy and Lansing to act with himself as the Executive Committee.

The questions selected for discussion at the next meeting were: "What are the honey-producing plants that may be raised to advantage?" "Best method raised to advantage?" "Best method for strengthening weak colonies after spring dwindling?" "Which is most profitable, box or extracted honey?" The Association adjourned to meet

on Tuesday, May 10, 1881, at 10 a.m., in same rooms. Chas. A. Pierce, Pres. C. M. Bean, Sec y.

Read before the California Convention.

#### Strong Colonies a Necessity.

S. D. BARBER.

The rapid progress made in apicul-The rapid progress made in apiculture in the last few years is remarkable. The increase in colonies and the production of honey has been marvelous to say the least of it, when we take into consideration the great loss of bees that California sustained in the years 1877 and 1879; yet apiculture is steadily moving on. The flora treasures of Southern California seem to be adequate to the great demands made more quate to the great demands made upon quate to the great demands made upon them, and many have come to the conclusion that there is a science in beekeeping that will pay the apiarist; but he will find that his success to a great extent very much depends upon his knowledge of that insect, the honey bee, and the natural laws by which they are governed....

The whole profit of apiculture consists in bearing the colonies strong. When

The whole profit of apiculture consists in keeping the colonies strong. When honey is abundant, a large apiary will fill up rapidly in the same place where a few weak colonies will barely make a living. If desirons of making bees prosperous and profitable, protect them from wind and wet, extremes of heat and cold, destroy their enemies, and leave them to enjoy a sufficiency of food, accumulated by their own industry, and if any are in want, a timely assistance should be rendered them, and doubt not you will prosper as a bee-keeper. Our snould be rendered them, and doubt not you will prosper as a bee-keeper. Our knowledge of bee instinct is such at the present time that no important point is longer a subject of controversy; and in the light thrown around the subject, no longer a subject of controversy; and in the light thrown around the subject, no branch of moral economy can be more definitely regulated, or conducted with such absolute success. The laws which govern these industrious little insects are peculiar to themselves, differing from those which govern everything else; yet they are simple, and easily learned by any close observer. But when a deviation is made from those laws, loss, sure and certain, must follow. To be successful, then, in the practical art, the science on which it is founded must be thoroughly understood. It is easy for any person to tell when their bees are prosperous, and it is just as easy to tell when something is wrong; but it is not so easy to tell what that something is. It is no longer a matter of doubt that the natural swarming of bees can be controlled, and get such increase by artificial means, secured as provide decived, and at the semetimes times. crease by artificial means, secured as may be desired, and at the same time a may be desired, and at the same time a crop of honey obtained according to the season. The early swarms are most profitable, but never be in too much haste to divide your bees. Your rule in artificial swarming should be, never cripple the strength of the colony where the crops is to represent the crops in the crops the queen is to remain, as she diminishes her laying according as the number of bees are diminished. I prefer to take brood and bees at different times from my hives as they can spare them, and have young and fertile queens to form my new colonies. Many valuable reference. The directic colonies are ruined by being transferred are sent with each one. from one hive to another in a wrong time, or by being divided without regard to the principles which should govern the matter to make it successful.

The Nebraska Bee-Keepers' Association will hold their Annual Convention, on the 10th and 11th of February, 1881, at Plattsmouth, Cass Co., Neb. Western Iowa bee-keepers are cordially Western 1000 500 invited to attend.

HIRAM CRAIG, Pres.

# Special Notices.

The Volume of the Best Journal for 1880, bound in stiff paper covers, will be sent by mail, for \$1.50.

Notices and advertisements intended for the Weekly BEE JOURNAL must reach this office by Friday of the

Constitutions and By-Laws for local Associations \$2 per 100. The name of the Association printed in the blanks for 50 cents extra.

BEE JOURNAL will be sent free to any names that may be sent in. Any one intending to get up a club can have sample copies sent to the persons they desire to interview, by sending the names to this office. names to this office.

rail It would save us much trouble, if all would be particular to give their P.O. address and name, when writing to this office. We have several letters (some inclosing money) that have no office, County or State. Also, if you live near one postoffice and get your mail at another, be sure to give the address we have on our list.

The date following the name on the wrapper label of this paper indicates the time to which you have paid. In making remittances, always send by making reinituances, auccaps send by postal order, registered letter, or by draft on Chicago or New York. Drafts on other cities, and local checks, are not taken by the banks in this city except at a discount of 25c., to pay expense of collecting them.

€ At the Chicago meeting of the National Society we were requested to get photographs of the leading apiarists, to sell to those who wanted them. We can now supply the following at 25 cents each: Dzierzon, the Baron of Ber-lepsch, and Langstroth. The likeness of Mr. Langstroth we have copied, is one formiched by his daughter, who saw furnished by his daughter, who says. "it is the only one ever taken when he was in good health and spirits." We are glad to be able to secure one of such a satisfactory nature.

😰 We will send sample copies to any who feel disposed to make up clubs for 1881. There are persons keeping bees in every neighborhood who would be benefitted by reading the JOURNAL, and by using a little of the personal influence possessed by almost every one. a club can be gotten up in every neigha cub can be gotten up in every neighborhood in America. Farmers have had large crops, high prices, and a good demand for all the products of the farm, therefore can well afford to add the BEE JOURNAL to their list of papers for 1881.

We have filled orders for quite a number of Binders for the Weekly BEE JOURNAL. We put the price low, 30 per cent. less than any one else could afford to sell them, for we get them by the quantity at wholesale and sell them. at just enough to cover the cost and postage, the latter being 21 to 23 cents, on each. We do this to induce as many as possible to get them, and preserve their Weekly numbers. They are extheir Weekly numbers. They are exceedingly convenient; the JOURNAL being always bound and handy for reference. The directions for binding

The Marshall County, Iowa, Bee-Keepers' Association will meet at the Court House in Marshalltown, lowa, on Saturday, Feb. 5, 1881, at 1 p.m. Subject for discussion: "Winter care of bees."

J. W. Sanders, Sec.

A Bee-Keepers' meeting will be held at Walnut Hill, Barren Co., Ky. on Saturday, Feb. 12, 1881. All are invited. 11. C. DAVIS, Sec.

#### SPECIAL NOTICES.

Premiums.—For a club of 2, weekly we will give a copy of "Bee-Culture; for a club of 5, weekly, we will give a copy of "Cook's Manual," bound in cloth; for a club of 6, we give a copy of the JOURNAL for a year free. Do not forget that it will pay to devote a few hours to the BEE JOURNAL.

What is the meaning of 'Dec. 81' after my name on the directionlabel of my paper?" This question has been asked by several, and to save answering each one, let us here say: It means that you have paid for the full year, or until "Dec. 31, 1881." "June 81" means that the first half of the year is paid for, up to "July 1st." Any other month, the same.

Owing to my increased business I shall not be able to attend to the bee supply business this year, and while thanking all my old customers for past favors, I would recommend them to buy their bee-keepers' supplies from Mr. A. II. Newman, of Chicago, as I know the orders will be despatched on the shortest notice.

Price 25 cents. - Sent on receipt of price, by

THOMAS G. NEWMAN, 974 West Madison Street, CHICAGO, ILL.

"The foremost religious newspaper of the United States."-JOSEPH COOK.

THE INDEPENDENT seeks the patronage of the public on three grounds, as follows:

1st. It is the largest weekly religious newspaper published in the world.

5d. It employs as contributors more able writers, at home and abroad, than any other weekly newspaper.

3d. It gives its readers a wider range of topics and more and fuller departments than they can find elsewhere in any journal.

THE INDEPENDENT consists of 32 pages, neatly cut and pasted. It is printed from clear type (we sterred type the pages weekly, and, hence, every issue is really printed with new type) and on good paper, and mechanically it is unexcelled.

There is no Question of prominence in religion, politics, science, education, finance, or any other department of buman knowledge which THE IN-DEPENDENT does not discuss. It has regular departments devoted to Biblical Research, Missions, Religions Intelligence, Book Reviews and Literary News, the Sunday school, Education, Science, Santary questions, Fine Arts, the movements of ministers, Personalities, News of the week, Financial and Commercial matters, uncluding Weekly Prices Current, Market Reports, Cattle Market, Dry Goods Quotations, Flowers and Faraning, and Insurance. In its religious department it gives news and starstice of all denominasions of Christians, everywhere. In fullness, accuracy, and comprehensiveness this department is unequaled. Several pages of stones and poems adapted to Old and Young are given every week, with a column of Puzzles.

From time to time Sermons by eminent ministers are published. The currant topics of the day are discussed in our editorial columns freely and vigorously. We are not a traid to state our opinions.

#### A General Law is Needed.

G. W. DEMAREE.

I regard the remarks of the editor of Tregard the remarks of the editor of the American Bee Journal. relative to the common practice of adulterating the food and drink of the people, to be "timely" in every sense of the word. It is highly gratifying to know that we have a man at the head of our favorite have a man at the head of our favorite bee paper who cannot be bribed by the hope of gain, nor driven by the horde of adulterators, their aiders and abettors, from the path of duty. This is no trifling matter to deal with. The adulterators have grown rich, and become securely intrenched while the people have slept. They can control legislatures, and make Congress itself gentle as fawns at their feet. This may be a humiliating confession, but it is neverhumiliating confession, but it is never theless true

The people, after their long nap, begin to rise and "shake themselves," but, like the strong man of old, their locks have been shorn and their strength

is not executed? Simply because the law contains no provision by which it can be executed. The Commonwealth of Kentucky, in order to make good a charge of violation of her laws, must prove the charge against the accused, and he must be tried before a jury of his countrymen, and not one juryman in a hundred (however intelligent he might be in other matters) would know glucose from "Adam's off ox." Hence the proof must be furnished by "expert testimony," and where are you to get an "expert" every time he is needed, unless provided by law? It appears to me that right here will be found the great problem to be solved. Any law that does not protect the interests of the whole people against the counterfeiters. testimony," and where are you to get an "expert" every time he is needed, unless provided by law? It appears to me that right here will be found the great problem to be solved. Any law covered that some of my bees were far that does not protect the interests of the whole people against the counterfeiters, and does not embrace a rigid system of inspection by which the law can be executed in the simplest manner, will, in my opinion, amount to but little in the end. But the thing is possible, and should be tried and tried again, till

etc. I thank the Doctor for those timely words; and also thank Mr. Scudder, for bravely speaking out as he does in the same issue.

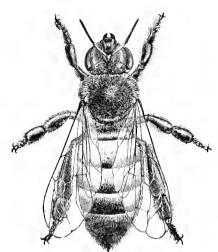

Christiansburg, Ky.

I am glad to see the subject of im-

Italian Worker Bee-magnified.

such a law is made available. At any rate, all these adulterators should be classed with thieves and robbers in all the statute books in the United States. In the meantime, however, the people must be educated to know the true from the false, and when this is done much will be done to drive the false "stuff" out of the market, and thus break down the counterfeiters. But it should be but, like the strong man of old, their locks have been shorn and their strength is gone. I doubt very much whether any law can be framed and enacted that will prove equal to the task of driving these scoundrels from their nefarious practice of tampering with everything that is capable of being adulterated.

The editor has referred to the statutory law of Kentucky, framed especially in the interest of the bee-keepers of the State. We have such a law in Kentucky, and tomost people it would seem to be everything that could be asked. It speaks out plainly in unmistakable words, and attaches a severe penalty; butit is nevertheless a dead-letter—dead as an Egyptian mummy. There is perhaps ten gallons of that vile emanation of satan—glucose—labeled and sold as "pure strained honey," to one gallon of the pure article, Not in Louisville alone is this imposition carried on, but I have seen it in the interior of the State—right in sight of my apiary, and in competition with its products.

It will doubtless be asked why the law

Take, all these adulterators books in the United States, In the meantime, however, the people must be educated to know the true from the statute books in the United States. In the meantime, however, the people must be educated to know the true from the statute books in the United States. In the meantime, however, the people must be educated to know the true from the statute books in the United States. In the meantime, however, the people must be educated to know the true from the statute books in the United States. In the meantime, however, the people must be educated to know the true from the false, and when this is done nuch will be done to drive the false, and when this is done much will be done to drive the false, and when this is done in the false, and when this is done in the false, and when this is done to drive the false. In the meantime, however, the people must be educated to know the true from the false, and when this is done to drive the false. In the meantime, however, the people due t

She was of the light variety, and her bees better honey gatherers than the dark. The next year I reared all my queens from the light colored, and was delighted with their beauty, but found that the workers from these young queens were not as good as those from the dark, and I now determined to try a few queens from my home-bred and selected the one that had given the best results the previous year, which was of

will be so. He gives as a reason for this, the severe pruning of nature, on account of the limited pasturage. We must, of course attend to this pruning, account of the limited pasturage. We must, of course attend to this pruning, even with a more rigid hand than nature. He says color and beauty are of no account with them; neither should it be with us. He says if Mr. Benton had not fed he would have lost all his bees. Here is a great trouble with the imported queens, they now come on the list with our dollar-queens; they are kept and used for the money there is in selling queens, not for their honey-gathering qualities. I will say here, that I do not believe it will pay any one to make this severe pruning for the purpose of rearing queens at one dollar each, and I would not advise any one to buy one of these cheap queens, though I do not doubt that there are many good queens sold for one dollar, yet there are so very many that are entirely worthless as honey-gatherers. I would rather pay some reliable person \$5 for a queen that I knew had been reared only for her honey-gathering and amibility, than to risk one of these cheap queens as a gift. Another reason I would give for homebred queens is that they have become acclimated to our country, which I believe to be very essential. When I take into consideration that there is not one of my neighbor bee-keepers that obtained over 12 lbs. of honey from their best colonies, while I obtained 63 from I colony, and averaged 23, I cannot help thinking that I have been well paid for all my pruning.

The past season had been a very poor

I colony, and averaged 23, t cannot help thinking that I have been well paid for all my pruning.

The past season had been a very poor one for honey in this section of the country. Many of the bees did not gather enough honey to winter on, and fully one-third are already dead. I do not believe one-half will survive the winter. One man had 15 colonies, and they are all dead. Many are becoming discouraged in the business, and will make no effort next year, although I look for a good season and have made arrangements for it, and if I am disappointed, I know I will be paid for my trouble in the pleasure I find in keeping and working with them. My bees are in good condition, and are wintering well so far. I packed them in chaff on their summer stands, in October, and was ready for winter when it came.

"When smooth old ocean and each storm asleep, Then ignorance may plow the watery deep; But when the demons of the tempest rave, Skill must conduct the vessel through the wave."

the dark, and I now determined to try a few queens from my home-bred and selected the one that had given the best results the previous year, which was of the dark race, and run them in this way to the third generation, always selecting the best. The results have been very satisfactory to me. The best queen I now have is of the third generation, and of the dark variety, with every appearance of a cross from the light, as the bees are of a much lighter color than the others. This colony gave me 28 lbs. more comb honey than any other—the average being 23 lbs., and I find it runs clear back to the imported, all the time gaining.

Prof. Cook thinks as soon as we cease importing queens, we will find our apiaries deteriorating. I will admit, if we keep up the dollar-queen business this

would be followed by a favorable winwould be followed by a ravorable winter. But in this we have been doomed to disappointment. October brought cool weather. November cold. December colder. January coldest, and now this 1st day of February, here in North-western Pennsylvania, we are fanned by the cool breezes of Greenland, and with winter is sifting ber groups with. and winter is sifting her snows with a lavish hand. My own apiaries I reduc-ed from 180 to 117 colonies, and one of that number has since gone where they'll

never hum any more.

1 winter in houses constructed for the 1 Willer in houses constructed on the purpose, on the plan described on page 185 of American Bee Journal, vol. 8, (1873); but the one there described has been replaced by a more substantial structure. The great need of our bees at present is a cleansing flight, but there seems no prospect of that in the near future, and should this stern old winter future, and should this stern old winter hold earth in his rey grasp for 4 or 6 weeks longer. I apprehend the severest thinning out of bees that the country has had since the introduction of movable comb hives and Italian bees. Hence my title "Riding the Billows," uncertain of the past.

In conclusion, allow me to say, that I am more than pleased with the Weekly. I did not like the idea of change of form, making it of unsuitable size for making a neat bound book, but its frequent vis-

a neat bound book, but its frequent vis-its give it a freshness it did not have as a monthly. "Long may it wave" and

## Pure Liquid Honey in Glass Jars, etc.

CHAS. F. MUTH.

In an age like ours, where one inven-tion follows another, and where chemistry has found even a substitute for mother's milk and babies live on it, it mother's milk and bables had on it, it is surprising that a common swindle, as practiced by New York and Chicago honey dealers, of putting a piece of comb honey in a glass jar and pouring over it pure glucose, could last as long as it did. I had a number of those beautiful welcome surprised and found that it did. I had a number of those beautiful packages analyzed, and found that it was not like Mr. Hoge states on page 37 AMERICAN BEE JOURNAL, present volume, "that so much glucose had to be used to keep it limpid," but it was found that the comb was the only honey in the jar, and that the liquid was pure glucose which had partaken of the flavor of the comb boney. Such is its danger.

glucose which had partaken of the flavor of the comb honey. Such is its dangerous character, that not having any flavor of its own it partakes readily of the flavor of a very small admixture. A gallon of pure maple syrup is sufficient to manufacture 10 gallons of choice maple syrup(?) Think of it! If I am wrong, I will stand corrected.

The public in general was, some time ago, although surprised at our large honey harvests, well disposed towards our product. "As sweet as honey," is a significant proverb. But the public has been "glucosed," and the interests of bee-keepers considerably damaged thereby. As honesty, as well as dishonesty is characteristic, it would be folly to suppose that adulterators should be esty is characteristic, it would be long to suppose that adulterators should be our redeemers. On the contrary, it re-quires the united efforts of honest bee-keepers and fair dealers to make front against every adulterator, and to expose

I have my serious doubts as to the innocent qualities of glucose, as it is only a few weeks since when I was informed

a few weeks since when I was informed by a friend that he saw in one of his med-ical periodicals that grape sugar was as-signed as the cause of Bright's disease of the kidneys in a patient. A druggist in our city who, I am sorry to say, adulterates with glucose most of the honey he retails, and with whom I remonstrated in regard to the matter, excused himself as follows: "I use pure boney only when making up prescripexcused himself as follows: "I use pure honey only when making up prescrip-tions; but I can sell a larger quantity of honey for a dime when adulterated." He is a good chemist, and about 3 or 4

granulating." My reply was that his recipe was not worth to me a picayune, recipe was not worth to me a picayune, because every sensible man expects pure honey to granulate, and would be disappointed at finding it otherwise; while those not yet acquainted with the nature of pure honey will soon learn. It would open a new field for adulterators which granulated honey wavents granulated honey prevents.

The present state of our honey market

shows plainly that granulated extracted honey will take the market in the very

noney will take the highest in the very near future, and not the liquid honey, while comb honey will remain what it is—a fancy article only.

I hear of great losses of bees in our neighborhood. One lost 60 colonies, and neighborhood. One lost 60 colonies, and sold me his combs, and quite a number of others have lost all they had, or nearly so. We had a pleasant afternoon last Sunday a week ago, when I made use of the time by looking over my bees, justifying myself by the verse, "When an ox or an ass has fallen into your well," etc. I examined 22 colonies, they had consumed very much of their they had consumed very much of their stores, but were in splendid condition some with hatching brood, and others with eggs and larvæ in all stages. Cold weather again ended a further examination.

Cincinnati, O., Feb. 8, 1881.

For the American Bee Journal.

#### Fertilizing Queens in Confinement.

W. ARMS.

I have tried the following course several times with good satisfaction, and wishing to have it thoroughly tested, submit it to the public. I use a hive similar to the Langstroth, entrance at the end, and frames hung at right angles to the entrance. Select a strong colony, put on a thin honey-board, covering all but the three back frames, which are covered with wire cloth. Fit on the upper story, which has a 3-frame nucleus confined to the back end with a division board, itself covered with a division board, itself covered with a honey-board; all the front part of the hives covered with glass, lined with musqueto netting, and over this the covor to the hive. The nucleus should contain two full frames of hatching brood, with all the young bees that adhere to them, plenty of honey, a small piece of drone brood ready to hatch, some young drones, (not too many), and a queen-cell not ready to hatch under 3 or 4 days; the two last named the finest to be had. Watch the gleen, and when she hatches shove the slide; the division heavy and shove the slide in the division-board and let all have a fly under the glass and return. When she is 3 days old remove the lid from 11 till 3 o'clock and let in the sun, but keep the queen shut up till fertilized.

Du Quoin, Perry Co., Ill.

For the American Bee Journal.

#### All Heave-oh-Heave.

W. T. STEWART.

Brother bee-keepers, the time has Brother bee-keepers, the time has come when we must act in one combined effort to stop the adulteration of honey with glucose. Delay is dangerous. Glucose men are working and amassing fortunes at our expense. A firm in Chicago are now manufacturing themsends of hereals of quinosal honey. thousands of barrels of glucosed honey. They are buying honey all over the country—even comb honey and extracting it, and mixing glucose with it at the rate of four barrels of glucose to one of honey, and shipping and selling it for pure honey, at a reduced price, and flooding the markets with it, and boasting of it, and say that it takes a good judge of honey to detect it. I get my information from one of the employees of said firm, and can prove it on them,

Now, I propose that we stop talking

fear it; then let Dr. Allen send a copy of the petition to each of the bee-papers to be published, authorizing each editor to receive the signatures and sign them; then let every bee-keeper in America send in his signature to some one of the editors, authorizing him to sign your name to it; then at a stated time let all the copies of the petition be sent to one party to be presented to Congress, praying for and urging their immediate action. Thus it can be done quick, and done well. Now is the time to work, before our business is ruined by the vile trash, glucose. Now let every man put his shoulder to the wheel and give one mighty heave, and we will be out of the mire again and look to a bright future. Eminence, Ky., Feb. 2, 1881.

> For the American Ree Journal. Our Bees.

JOHN CRAYERAFT.

Our bees are about all gone, dysentery has taken about all of them; out of 46 colonies that I put away the last of Oecolonies that I put away the last of October, I have but 3 left to tell the sad fate of their comrades. About 3 weeks ago they were apparently all right and alive, but were very restless and measy, but could not get out the weather being so cold and stormy, until last Sunday, Jan. 30, being warm and pleasant so that bees were out, and had a good cleansing flight—that is, what were alive. In examining the hives, I find them all dead and covered with their excrement, in one stinking mass among the combs and on the bottom of the hive. They had consumed but very little of their stores since I put them away, about the nad consumed but very little of their stores since I put them away, about the last of October, there being frames of sealed stores in nearly all the bives. 1 can attribute their loss to no other cause but there being so much of the juice of peaches and apples stored late in the fall, which with what fall honey was gathered formed a thick jelly-like formation containing acid and an alcoholic substance, and with the long confinement from about Nov. 10th to Jan. 30th, with only a few hours during all that time when they could get out, and then only to fall on the frozen ground and

only to fall on the frozen ground and perish.

Out of near 1,000 colonies in this county reported last October, I think I can safely say that there will not be 50 colonies left, from the reports I have gathered the past few days. In some localities in this county there is not a colony left, especially is this the case where the most peach orchards are, and where there were no peach orchards near there are a greater number of colonies there are a greater number of colonies

alive.

This is not a very flattering prospect This is not a very nattering prospect for keeping bees here this year; but we are not without hopes, for I am making preparations to get bees from the South. I think we have as good location in this county for producing honey as there is in the State. Success to the AMERICAN BEE JOURNAL. Salem, Ind., Feb. 2, 1881.

For the American Bec Journal.

#### One-Piece vs. Dovetailed Sections.

S. D. RIEGEL.

The article on "Hive and Section Making." by James Heddon, in the American Bee Journal of Feb. 2. AMERICAN BEE JOURNAL of Feb. 2, contains very much that I can heartily endorse, in fact expresses very nearly my own views, especially that portion of the article relating to hives; but when it comes to sections I feel like putting in a strong protest. I quote as follows from the article: "I object to the all-in-one-piece section, and do not use them because of that naughty little sharp corpore that is always catching and emising because of that naughty little sharp corner, that is always catching and causing the next section to leak, when raised up and pushed down into the case; also, because they are too liable to break, both at the time and after bending, and are not so true and solid as good dovetailed work." Now I do not know what kind of all-in-one-piece sections friend Heddon has tried, but I do know that in all that I have tried or used I have never observed "that naughty little corner" to which he refers, in fact, I do not know what sort of a corner he can

mean. I have noticed no difference as to corners between the all-in-one-piece or dovetailed sections. Again, "they are too liable to break, both at the time and after bending, and are not so true and solid as good dovetailed work." I feel so confident that friend Heddon is mistaken in these last assertions that I would be willing to have a practical test made of the matter by each of us furnishing 500 sections to be placed in the hands of ten experienced bee-keepers, giving each of the ten 50 sections of the doubt in the hands of the companion of the sections of the doubt in the properties. dovetailed and 50 of the all-in-one-piece sections, and with the agreement that the Editor of the A. B. J. select the ten bee-keepers from those who are not insections, they to report at the National Bee Convention next fall, and if the de-cision is not in favor of the all-in-onecision is not in favor of the an-in-one-piece section, two to one, a premium of \$10 to be paid by the National Bee Association—if they are willing to con-tribute it—shall be paid to friend Hed-don, but if two-thirds or more of the 10 don, but if two-thirds or more of the 10 bec-keepers decide in favor of the allin-one-piece sections, then the \$10 shall be paid to me. The decision to be based on strength, solidity and trueness of the sections, I make this offer, not for the \$10, but that bee-keepers may know the facts in the case. If dovetailed sections are better than the all-in-particle, was chould use them. If not one-piece, we should use them, if not, we should discard them, as they are we should discard them, as they are more expensive to make and are not so handsome as the others. What say you, friend Haddon? Don't you think we had better have this matter decided as proposed above and let the bee fraternity be benefitted by the decision? Ådelphi, O.

The suggestion of a test in the matter of sections is a very good one; but inasmuch as both Mr. Riegel and Mr. Heddon are interested in the sale of the sections preferred, we can hardly see the justice of the proposition that the National Convention contribute \$10 for advertising special wares. Rather would we see the contribution of \$10 go to the National Convention by the fortunate contestant, who could well afford to do so, considering the notoriety he would gain thereby.-ED.]

For the American Bee Journal.

#### My Experiments Wintering Bees.

C. THEILMANN.

I have for the past 10 years been experimenting in wintering bees, both in and out doors, but as yet have not found an infallible way, in all cases and circumstances against some losses, in wintering the best but fight they door tering my bees; but find the out door wintering, packed in chaff on summer stand, less trouble and loss, as cellar or prepared bee-house, for this climate; it is quite a job to carry 140 to 150 colonies (from and to a hill-side) at least once or twice in and out of cellar or bee-house, to give them a cleansing flight when the weather is warm enough, and if they are weather is warm enough, and if they are left in doors 31, to 4 months, they will get very aneasy on account of getting so heavily loaded with feces, and to my experiments, perish, or get the so-called dysentery, before they can be set out on their summer stand, in the spring; therefore I have quit wintering in-doors entirely; I have packed my 147 colonies with chaff, on summer stand, in Langstroth hives, again, this winter, and as another experiment, I have partly covered them with snow, over the packing, with an open space in front from the entrance, 1 inch high by 6 inches wide; they are all alive yet and seem to do well, with the exception of a few, in whose entrance ice threatened to close the passage of air, which I melted away whose entrance ice threatened to close the passage of air, which I melted away with a hot iron, but I roused up the bees badly, in doing so. Some of those colo-nies have been uneasy since. It has not been warm enough here for bees to have a cleansing dight (and the few which try to fly drop on the snow never to rise) ever since the latter part of October; it has been steady cold weather and a few honey only when making up prescriptions; but I can sell a larger quantity of honey for a dime when adultcrated." He is a good chemist, and about 3 or 4 let Dr. N. P. Allen, the president of the years ago he offered me for \$10 a recipe to keep pure houey from granulating, and showed me, as a proof, a bottle of liquid honey he had kept exposed to the cold all winter. "This is not adulterated ting," he explained, "but merely adding a little drug which imparts no flavor to the honey, but is certain to keep it from 1 have read Mr. Doolittle's article. "Covering bees with snow," in the BEE JOURNAL of Feb. 2d. with much interest, on account of experimenting myself with snow this winter. I would like to ask Mr. Doolittle, through the BEE JOURNAL, the question, whether he covered the whole hive all around with snow; whether he left any uncovered space in front, or to the entrance; and how long he left them so covered?

covered?

The fore part of last summer was very The fore part of last summer was very poor for bees here. I started with 125 colonies; some of them were very weak and I had to feed them from June 10th to the 18th, from then to the 29th they made their living, when basswood commenced to blossom, which was so abundant and filled with nectar, that they filled up their hives, besides getting about 3,000 lbs. of surplus honey.

My bees are nearly all hybrids, with a few exceptions of blacks. Fourteen years ago this winter, I found a colony of blacks or natives, or the so-called wild bees. By chance 1 chopped down a tree in which they were hiving; this was my first colony. From them, and some other wild bees that came to my premises in swarming season, I have

premises in swarming season. I have reared my stock. How they got mixed with Italians I do not know, the nearest Italians kept around here, were about 5

Theilmanton, Minn., Feb. 5, 1881.

LATER.—Feb. 8.: Within the last 4 or 5 days, considerable ice gathered in the entrances of my bives. I have tried another way to loosen or melt it away, in which 1 succeeded; it was done by covering the ice with salt. I have spread it on in the evening, and the next morning the ice was melted or loosened so that it could easily be taken away; while on a few hives with icy entrance that were not salted (on purpose for trial) the ice not salted (on purpose for trial) the ice froze solid. It was 20° above that night. This does not disturb the bees at all, and is a far better way than the above des-cribed iron. Bees in this vicinity that are out-doors, unprotected, are nearly all dead.

No trains or mail have gone east from here since the 4th inst., and the country travel is almost entirely stopped on ac-count of snow-drifts. Weather has changed, and is almost warm enough to-day for bees to fly. They want it badly. Success to the BEE JOURNAL, I read it with much interest and pleasure.

Doing Well.—As I have observed no report from this part of the country, I thought I would send you a few lines. I commenced the spring of 1880 with 10 weak colonies and no honey; I increased to 14, obtained 150 lbs, of comb honey and 70 lbs, of extracted, and my bees are well supplied with honey for the winter. I use the Langstroth hive. Bees in this locality had no flight for 7 weeks, lasting till Jan. 28, which was a warmer day. Then I raised the hives and swept the dead bees out. There were from a small handfull to a pint under each hive, and in one the bees were all dead, leaving about 20 lbs. of honey in the hive. My bees are on the summer stands covered with chaff. Did the colony mentioned starve or freeze. Doing Well .- As I have observed no the colony mentioned starve or freeze, and is the amount of bees I swept from the others liable to injure them much? ALBERT LONG.
Iola, Ill., Feb. 1, 1881.

The bees probably starved—that is, a "cold snap" came on while they were removed from their "base of supplies," and they perished. If your colonies are strong, the loss of from a handful to a pint each will do no harm.—ED.]

Coldest for Nine Years.—The winter so far has been the severest known for nine years in this part of the State. The cold weather commenced in November, nine years in this part of the State. The cold weather commenced in November, as he says he has his bees packed in straw or chaff. I have tried the chaff theory to my satisfaction, and find some their hives for 3 months, and the prospects are that they will be for 2 months

their bees. Success to its efforts.

HARRY G. BURNET.

Blairstown, Iowa, Feb. 5, 1881.

Early Work.—At this date my bees are busy bringing in pollen, and the prospect is very good for a yield of

honey the coming season.

G. B. WALLACE.
San Bernardino, Cal., Jan. 30, 1881.

Do Woolen Blankets Absorb?—This year in packing my bees for the winter, I put on thick woolen quilts over the frames and below the chaff cushion. Have had considerable trouble with ice forming on the bottom-board so as to obstruct the entrance. (the summer entertine) torming on the bottom-board so as to obstruct the entrance (the summer entrance 15x4 in. is open with no upward ventilation), and I fear the woolen quilts repel the moisture instead of letting it pass through to the chaff. Will the BEE JOURNAL tell me is this so, or the field fournal ten me is this so, of is the trouble caused by the long continued cold? They have had no flight since early in November. Am preparing for a big funeral, at which all poor hig for a big function at which an poor-bee-keepers will be sympathetic mourn-ers. Am glad the "new departure" is a success. "Growth" is the world's watch-word. E. M. R. Flint, Mich.

[Woolen blankets will absorb the moisture very nicely, and where there are 2 or 3 used in one hive, it is not uncommon to find the upper ones quite wet, while the lower blanket will be comparatively dry and quite warm. The trouble is undoubtedly caused by the intense cold and long confinement. A correspondent in this number suggests that the sprinkling of salt in the entrance will prevent the ice formation. We have made no experiments in this line, and cannot say whether the saltwater or brine will be distasteful to the bees, but presume it will not. Some bee-keepers go so far as to claim that salt is beneficial.—ED.]

Bee Pasturage, Etc.-I am glad over-

stocking and growing bee-pasture is receiving so much attention by writers in the BEE JOURNAL. When I located in the BEE JOURNAL. When I located my apiary here I think there were not my apiarv here I think there were not to exceed 25 colonies within a radius of 3 miles of me. At that time there was little trouble to get good results from bees, with little attention and little knowledge of scientific management. But now there are, I presume, no less than 400 colonies within the radius above mentioned, and we find it requires the best of aniary amaratus and the most. mentioned, and we find it requires the best of apiary apparatus and the most scientific management, coupled with "eternal vigilance," to get partially sat-isfactory results. I live by a grove of young timber. Scattered through it were nice young bass-wood trees; on my land I have cut away the other trees from around them, till now I have 400 nice trees, from 6 inches to a foot in di-ameter. Just one-half mile from my trees lives a man who keeps about 100 colonies. He had more bass-wood on his land than I had; but he is stripping his place of bass-wood, cutting it into cord-wood. I asked him to preserve his trees for his bees, but he replied: "You trees for his bees, but he replied: "You and my other neighbors have saved enough to keep my bees." So it goes. I sowed last spring, five acres of melilot, but we had a terrible wind which blowed nearly all the loose dirt and seed into the fence corners, so I have not a half a stand, but I shall let it stand and make what it will. I am out of seed or I would saw five acres more next spring. I would sow five acres more next spring. I believe this winter will cause the loss of half the bees in western Iowa. I see friend Martin, in a recent number of

honey, but it was so hot no one could eat enough of it to make him sick uneat enough of it to make inin sick unless he was a tobacco chewer. I never obtained any of it myself, as I am not near any low land. All I have seen comes from localities near swamps. I am asked almost daily by those who have some of it, what it is gathered from, and from the best observation I can make, I think it is gathered from a kind of swamp milk-weed. There is no kind of swamp milk-weed. There is no laurel in this section. The hot honey seems to be stored by the bees only in seasons of great searcity, as I never knew of any complaint during good seaknew of any complaint during good seasons. I am so pleased with the Weekly Bee Journal. It is certainly a great success, so far as your readers are concerned at least, and we hope it will be equally so to you.

WILLIAM MORRIS.

Anderson, Iowa, Jan. 31, 1881.

[The hot honey spoken of is probably collected from the prickly ash (Xanthoxylum Americanum), which grows in great abundance on the lowlands in the heavy timber of nearly all the Northwestern and Central States. We have also noticed much of it in Missouri, Kentucky and Tennessee. The prickly ash is a profuse bloomer, and bears many berries of a very sharp, pungent taste. We have seen bees on the flowers, but never to sufficient extent to induce the belief that it produced any amount of honey; it might be, however, in cases of great searcity of honey, that bees would store enough from it to affect and spoil all the surplus.—Ed.]

How will they come out?—It has been so cold here ever since the 10th of November that bees could not fly out without freezing. About the 20th of November I moved my bees one-half mile and placed them under a hay-shed fixed on purpose for them, under a high cowshed. I have Mitchell's hive, I guess it is, it came from McDougal, of Indianapolis, Ind. When I moved them I closed them up with the division boards as well as I could, and covered the closed them up with the division boards as well as I could, and covered the frames with dry cloths, mostly woolen. The hives then were full of frost, and shortly afterward I found them damp; I dried all the coverings, and now they all appear dry and as lively as in summer. I am a beginner with bees. I purchased 6 colonies last spring, and they increased by natural swarming to 21. I obtained over 100 lbs. of comb honey from the first new swarms. I am somewhat worried since seeing in the Journal the danger of disturbing them in winter. Some of them do not smell very sweet now.

smell very sweet now.
M. O. TUTTLE.
Saratoga, Iowa, Jan. 31, 1881.

Good Prospect for Basswood.—Hearing that the bee-keepers of Wisconsin think that most of the basswood in their State is dead, on account of the extreme cold weather we have had during the past 3 months, I would say that I have examined the basswood in this vicinity very closely, and find it all alive; buds are swelling now, and look as healthy as ever. The bees, as a general thing, are doing very poorly, and I believe that one-half of the bees that were put into winter-quarters last fall believe that one-half of the bees that were put into winter-quarters last fall are dead, those alone surviving that were well packed on summer stands. It froze up here about Nov. 11th, and there has not been a day since that the thermometer indicated over 30 above zero at noon, and twice it has been 40 below zero in the morning. The ice is now 30 inches thick here on the Trempealeau river; but, not with standing the extreme weather, the bees that were well backed weather, the bees that were well packed

to come. I think that probably % of the bees in this section will be dead by the 1st of April. It is thought that the season of ISSI will be a good one for bee-keepers—I certainly hope so. The Journal is exerting a very good induces on the bee-keepers of this section as can be seen by the care they give their bees. Success to its efforts.

dead on their summer stands. I used to be wintering, number of wild flowers; white clover is useful to with the winter, I wery abmodant, and dandelions grow but while I lost none in the winter, I wery abmodant, and dandelions grow but while I lost none in the winter, I wery abmodant, and dandelions grow but while I lost none in the winter, I wery abmodant, and dandelions grow but without end. The creeks are lined with willows, which furnish the best of bees ideable of that peppery homey Prof. We have the basswood, which is praction as can be seen by the care they give their bees. Success to its efforts. number of wild flowers; white clover is very abmidant, and dandelions grow without end. The creeks are lined with willows, which furnish the best of becasturage in the spring; besides these, we have the basswood, which is practically boundless in extent, as the bill-sides are covered with young basswoods from 1 to 15 feet high. I have introduced alsike clover in my section, that is that place where my farm is, about 9 miles from Arcadia. The only question here now is: Cam bees be wintered with surety in this place? If so, then the amount of honey that can be produced in Western Wisconsin is simply enormous.

R. A. Morgan.

Arcadia, Wis., Jan. 31, 1881.

Complimentary.—Our bees had a good "dy" on the 30th of January, being the second flight that they have had since second flight that they have had since the 1st of November. Such a winter as we are experiencing is a new thing to the oldest inhabitant. The farmers who keep bees, or rather let the bees keep themselves, have lost fearfully, perhaps one-third—equal to the increase of last year—has already perished, and more will go. 1 could not express to you the real pleasure it gives me to see the AMERICAN BEE JOURNAL "all fresh" once a week. I confess that I had my doubts at first as to whether a weekly bee paper could keep up as high a standard of bee literature as that to be found in a well edited monthly; but in this I was agreeably mistaken. The matter found in each weekly issue has matter found in each weekly issue has matter found in each weekly issue has been in every respect equal to that found in the monthly, before the change.

G. W. DEMAREE.
Christiansburg, Ky., Feb. 3, 1881.

[We are fast reaching the fruition of our ambition-i. e., to make the Jour-NAL so attractive that the prejudices of the few against change in form, and the doubts of many about keeping up its high standard, will be absorbed in its increasing interest.—Ed.]

To Prevent Robbing.—My bees have not had a fly for 3 months, the weather has been so cold and steady; we have a thaw to-day, and I hope they will soon get a chance to fly. I think my bees are all alive. It seems there still are bee-men who do not know how to stop the still are bee-men who do not know how to stop the still are bee-men who do not know how to stop the still are bee-men who do not know how to stop the still are bee-men who do not know how to stop the still are been still a still are been still a s robbing, so I will give my remedy. Use a wet rag folded up and laid at the entrance, regulate according to the extent of the case on hand, and you will tent of the case on hand, and you wan never fail to stop it. I have practiced this plan for 2 seasons, and never failed in a single instance. Bee-keepers feel somewhat gloomy in this locality on account of the hard winter.

II. S. HACKMAN.

Peru, Ill., Feb. 8, 1881.

Peru, III., Feb. 8, 1881.

Hard on Bees.—This is the most severe winter on bees that I have had in my 24 years' of experience. My bees gathered very little honey during the fall season, except that which was gathered from fruit and a cider press which was only a few hundred yards from my apiary. The unnatural food and cessation of breeding early in the season, is the cause of heavy loss during the severe weather from Dec. 29th to the present time (the weather still being very cold). I found one of my best colonies queenless; in looking over a colony apparently dead, I found that the queen with a few dozen workers, with proper care would revive. I took both hives into the house and determined to save the one if possible. After getting them thoroughly warmed. I introduced the queen in the queenless colony, on the evening of Feb. 2, with the theromometer 6 below zero. Would it not be a good plan for all the beekeepers to report next spring just how many colonies they had last fall, and how many they have left when the loney season opens? Is there a stronger argument necessary for the hee-keepers to teach them that healthy food and proper care in putting them up for winter is a positive necessity? Surely, my proper care in putting them up for winter is a positive necessity? Surely, my fellow bee-keepers, we must learn some-thing from the severe lesson we are getting, if we expect to succeed bett hereafter. J. H. Bupp. Glen Rock, Pa., Feb. 2, 1881.

#### THOMAS C. NEWMAN.

EDITOR AND PROPRIETOR.

CHICAGO, ILL., FEB. 16, 1881.

#### The Eastern Conventions.

Having promised to attend the Convention at Andover, O., on the 8th and 9th inst., we concluded to go to the Convention at Utica.  ${f N}$  .  ${f Y}$  ., and attend that at Andover on our return.

It will be remembered that the Convention at Utica, last year passed resolutions denouncing the BEE JOURNAL and itseditor, and we thought we would like to see what course they would pursue this year. Of course we were wholly unexpected, but were received very cordially, and by vote were requested to address the Convention on the matters at issue.

Being fully assured of the wisdom of the old motto-" Truth wears no mask, bows at no human shrine, seeks neither place nor applause—she only asks a hearing"-we accepted the invitation, and in the light of facts and incontrovertible arguments, we discussed the whole subject. The result was that the Convention voted to drop the matter entirely, and devote its time and energies to the discussion of practical issues. cordially invited us to participate in the discussions, and unanimously elected us an honorary member of their Society, Thus ends the recent "unpleasantness," to the satisfaction of all concerned.

The general expression was that of gladness that we were present, and all (without exception) endeavored to make the Convention as pleasant and profitable as possible. A report of two days' proceedings may be found on another

At Andover, O., we met with many old friends, and had a very pleasant and profitable meeting. A report of issue of the BEE JOURNAL.

The President of the British Bee-Keepers' Society, the Baroness, Lady Burdett-Coutts, took to herself a husband last Saturday. The happy bridegroom is Mr. W. Ashmead Bartlett, a worthy American gentleman. The AMERICAN BEE JOURNAL presents its compliments, and wishes the happy pair a very enjoyable future. The Lady is known throughout the civilized world, as one of the greatest public benefactors that ever lived.

The Indiana Farmer says that bee-culture is becoming a profitable indnstry in Texas, especially in the valleys of the Brazos and Colorado rivers, whose extensive bottoms furnish a wide range for the honey-gatherers. Southern paper says "quite a number of enterprising men have given it their sole attention, finding the industry vastly more profitable than cotton

Floods are now the order of the tween the two. day everywhere. This has been the the memory of the oldest inhabitant.

#### Apis Dorsata of Java.

We are in receipt of the following letter from Mr. Thomas, a gentleman for whose opinion we have much respect:

Coleraine, Mass., Feb. 1, 1881 Coleraine, Mass., Feb. 1, 1881.

I am not yet convinced that the Apis dorsata is incapable of domestication, notwithstanding all that has been said in the JOURNAL to the contrary. I do not think the fact of their building their combs on the limbs of trees in the year rains is any proof that they cannot open air, is any proof that they cannot be domesticated; doubtless the Italians would do the same if left to themselves

would do the same if left to themselves in such a warm country.

Mr. Cary, some years ago, instructed a missionary, who was about to return to the Island of Ceylon, where this bee is also found, how to prepare and pack a colony for shipment, in the hopes that he would send him one on his return. But as he never received the bees or heard from him, it is supposed that he was unable to procure them.

In conversation with a missionary

was unable to procure them.

In conversation with a missionary some time since, I inquired about the bees in Java, and he said that he knew of no reason why they could not be "tamed," as he expressed it. There was a colony found in the stump of an old tree in a four ishing condition, which the patients smoked out and obtained as the natives smoked out and obtained a amount of honey

The natives ascend the tree by pegs driven into the wood, and after smoking the bees off of the combs, cut them off let them down by a cord to the ground.

was very much interested in Rev. Mr. Langstroth's article on the dorsata, published in the JOURNAL, vol. xiv., page 417. He was very much interested in this bee, and I believe if his health had been restored, he would have kept this subject agitated until there was some move towards importing them.

As for their stinging qualities, I for one would be willing to be stung some, if they would prove as good honey gatherers as I firmly believe they would. If Mr. Hawley would give up his "stingless bee" enterprise, and direct his attention to the *Apis dorsata*, I think it would be better for him and all the rest

I look forward to the importation of this bee, at an early day, into the United States, and should my hopes reach fruition, and the dorsata should be able to reach the hidden nectar in the red clover, it will prove a mine of wealth to the bee-keepers of the United States. E. A. Thomas.

We are not aware of having written a word to discourage the importation of this Convention will be found in a future the Apis dorsata, or any other race of bees which may by any possibility improve, or be an improvement upon, our present excellent Italians; but, rather, are most desirous to have a fair trial given to all—the Cyprian and Palestine bees, Apis dorsata, Apis zonata, and even the Caucasian bees. American bee-keepers are not to be satisfied with anything short of the best, come from where they may, and cost what they will. In making up the verdict, all the points must be taken into consideration, and much time consumed in deciding which are best. Those which would be best adapted to Norway, Sweden and Russia might not prove best for our latitude and flora, any more than would the bees from Java, Cevlon or Africa, Research and exhaustive experiment may demonstrate that it is not a pure race of bees we want, after all; that we may find most suitable a race or variety combining the characteristics of those of the two geographical extremes -a variety capable of withstanding the rigors of a Russian winter and the scorehing drouths of an African summer-or, at least, an average mean be-

We have no doubt the queens from severest winter, the world over, within | Palestine have already proven superior in one point at least—that of greater ble report from this committee.

prolificacy than anything we have heretofore possessed. Should, however, the theory of certain deterioration in this country prove correct, as is claimed in regard to the Italians by an eminent scientist and scholar, then there is no permanent advantage gained by their introduction. We would be obliged, at last, to verify Mr. Robinson's record (see 9th paragraph, 3d column, page 46 of Weekly Bee Journal) by substituting some approved foundation. We are satisfied, however, no good stock, whether bees or anything else, will deteriorate in the hands of our intelligent and emulative breeders, so far as practical purposes may be at issue. Nor do we doubt that the Cyprians may possess some very desirable characteristics that can be utilized with advantage by our apiarists; but what they may be we are not yet prepared to say. A better acquaintance with Apis dorsata and Apis zonata will certainly develop traits that can be borrowed with great profit by the bee-keepers of America, and we await their introduction with hope and somewhat of impatience. Meantime. we must relax no effort to improve our present desirable strains; systematic compilation of data, scientific application of knowledge, and careful selection of the best, and Apis Americana will wave its untiring wings over the flowers of Europe, sipping as well the dewdrop from the rose of Sharon as the nectar from the lilacs of Italy, the rosemaries of Spain, the clovers of Holland, and the goldenrods of America.

Let the verdict of apiarists be favorable or unfavorable for the Cyprian and Syrian bees, Messrs. D. A. Jones and Frank Benton deserve the thanks of all for their untiring perseverance, and it only awaited their latest enterprise (the trip to Java, Timor and the Phillipine Islands) to record their names among the benefactors of the age.

While much care has been taken to breed our bees up to the requirements of the floral world, and one (Capt. W. Williams, of Ohio) claims to have developed their tongues to 11-32 of an inch in length, our bee-keepers have neglected to grow the flowers to the requirements of their bees. The suggestion of Dr. C. C. Miller, President of the N. W. Bee-Keepers' Association, that perhaps the quickest way to adapt the bees' tongues to the red clover would be to shorten the flowers to the length of their tongues, seems to have been overlooked. The Alsike is undoubtedly a hybrid, perhaps white and red clovers crossed, and if the latter can be hybridized it can be grown with shallower nectar-tubes. In Germany experimenters are acting on his hint, with satisfactory prospects of success. Mr. Hasty, of Ohio, is also experimenting with the same object in view. It is a subject worthy of more than a passing thought, and deserves studied consideration.

At the Utica Convention we met Mr. J. II. Nellis, the genial editor of the Bee-Keepers' Exchange. We are pleased to notice the strong position he takes against the adulteration of honey. Mr. L. C. Root, the able ex-President of that Association, with Mr. Nellis as alternate, was appointed to wait on the New York Legislature, in person, and demand that the law against adulteration of sugar and syrups should also include honey. We hope soon to give a favora-

#### Moisture Absorbents in Bee Hives.

In our latitude. 38th parallel, the cather is so changable that I often weather is so changable that I often think we have as much trouble to winter bees successfully as they do in Minnesota and Wisconsin. Their frequent flights through winter cousume much honey: the long rains (winter) and sudden freezing keep the insides of hives in anything but a healthy condition for the bees. This led me to study the best the bees. This led me to study the best material to overcome the trouble, and I see Mr. C. Lover, of Maryland, has sounded the key-note and whole secret of dry hives, viz: I have heard old soldiers say they were "as dry as a lime-kiln." The chemist uses lime over his alcohol to abstract the last drop of water contained in it, thus making it absolute. So we must do to protect our bees—use anything, patented or not, so we accomplish the saving of our bees.

Now, I go further than Mr. Lover; 1 lath and plaster my hives I inch thick all around inside, with mortar made of sharp sand and plaster of Paris; this smarp sand and plaster of Paris; this makes it cool in summer, warm in winter, and with dry lime in the cushion over their frames, I feel, from this winter's experience, that I have found it. at 1 may 10 man 1. I put 1 small colony in my plastered hive last spring; they did well, but owing to the failure of honey secretion they gathered no surplus. I examined all (20 classics) at the second they have been been second to the second of the surplus. colonies) a few days ago, and the "lime-alln hive" was the only one containing pure combs—every other one was more or less moldy; but I never saw bees doing better than under the lime cushion.

I use gunny sacking, with cheap cotton batting laid over that, then sew 3 sides and put in about 1½ inches lime. I use air-slacked lime, thoroughly dried in the cook-stove oven before putting it in the real in the sack of in the cook-stove oven before putting it in the cushion. It is not a little singular how often the same idea possesses the minds of individuals very distant geographically, and in very the minds of individuals very distant geographically, and in very much the same way. As I was making the ex-periment of the amount of carbon dioxide per hour exhaled by different persons (fat and lean) with the limewater test, when the bees came into my mind, and I went straightway and made a deputator for one hive with the best of results. I hope others will try these interesting experiments.

W. VAN ANTWERP, M. D.

Mt. Sterling, Ky.

The matter of absorbents has been a cause of considerable experimentation with us in the past, and we are exceedingly glad to find it engrossing the attention of scientific men such as Dr. Van Antwerp, and others. The winter now closing is demonstrating very satisfactorily that it will not do to depend wholly on chaff-packing under all circumstances, nor is it possible or convenient for all to winter in good cellars. for the reason that good cellars are not available to all. Again, there is much trouble entailed in cellar wintering, such as the proper preparation of the cellar, placing the bees within it, removing them to the open air for a flight if perchance the weather should moderate to allow of it, then putting them back, and again setting them on the summer stands when winter is through, in all of which operations there is a possibility of seriously disturbing the bees at times when it is very hazardons to do so. Also, many trace serious spring dwindling to the wintering of the bees in the cellar as the prime cause, and are anxiously looking for a more satisfactory method, and devising schemes and experiments for out-door wintering. So far, however, chaff-packing has proven no less unsatisfactory, and many this winter will nearly lose confidence in it, and drift around for a substitute which will be more certain in its results and less expensive in prac-

Foreseeing the need or demand for a radical change, we instituted a series of

lime as a dryer, and sulphuric acid as an absorbent. The lime we employed in a crude—state—that is, unslaked—but found it too heating when used in any quantity, and not absorbing enough it used in small quantity. The sulphuric acid was much more satisfactory in its description of the pleasure of said county, as a commissioner, who shall hold his office during the pleasure of said count; and a record of such order of county and record of such order of county and a record of such order or description of the duty of the passage of probate on the receipt of the passage of probate on the lime as a dryer, and sulphuric acid as an results. We found by the use of one ounce of sulphuric acid, diluted with onnee of sulphuric acid, diluted with the same quantity of water, placed in a saucer, and put on the top of the blanket, with a screen or wire cloth covering to keep out the chaff, then covering ing to keep out the chaff, then covering all with packing, there was no perceptof all the hives thus prepared, every comb was perfectly dry. So well pleased were we with the result, that we intended preparing ten last winter in the same manner; also, to thoroughly try slaked lime in the manner as above described by Dr. Van Antwerp, but a very busy fall, and the early advent of winter, entirely prevented the prosecution of further experiments. We intend to thoroughly test both methods, as also plaster of Paris or side-walls for several colonies, and will give results hereafter. Meantime, we suggest that the Doctor ible moisture to be found in the hives. Meantime, we suggest that the Doctor test sulphuric acid. We are almost persnaded he will like it much better than his "lime-kiln."

#### Suppression of Foul Brood.

At a meeting of the Southern Michigan Bee-Keepers' Association, held at Battle Creek, on the 9th inst., the following preambles and resolution were adopted, as reported by the Committee. approving of the bill now before the Legislature of that State for the suppression of foul-brood:

Whereas, It appears in evidence that a bill has been presented in the House of Representatives which has for its object the suppression of the disease and

ject the suppression of the disease and scourge among bees known as foul-brood; and

Whereas, Said bill has been placed on file and numbered 54; therefore,

Resolved, That as a sense of this meeting, we hait this action on the part of the State Legislature as timely and good and would strongly urge the passage of said bill, or a similar one, looking to the suppression and extripation of this dreaded disease among bees, believing that it is a proper subject for legislation, for the protection of those engaged in for the protection of those engaged in bee-culture.

L. McCoy, E. B. Southwick, Committee, J. B. Ide,

The following is a copy of the bill now before the Legislature of Michigan, referred to in the above resolution. It was introduced in the House on the 3d inst.. by Mr. Root, and is recommended by the Committee on Horticulture:

A B1LL to prevent the spread of Foul Brood among bees, and to extirpate

the same.
Section 1. The People of the State of Michigan enact, That it shall be unlawful for any person to keep in his apiary any colony of bees affected with the contagious malady known as foul brood; and it shall be the duty of every bee-keeper, as soon as he becomes aware of the existence of said disease among his bees, to forthwith destroy or cause to be destroyed all colonies thus affected.

destroyed all colonies thus affected.

Sec. 2. In any county in this State, in which foul brood exists, or in which there are good reasons to believe it exists, it shall be lawful for any five or more actual bee-keepers of said county to set forth such fact, belief or apprehension in a petition addressed to the judge of probate, requiring him to appoint a competent commissioner to prevent the spread of said disease and to vent the spread of said disease and to eradicate the same; which petition shall

experiments two years ago, both with records of the court where such applieation is made.

of such order of appointment, and revocation, when revoked, shall be filed as

from whom he received his appoint-

Sec. 5. Upon complaint of any two mediately notify the person to whom said bees belong, personally or by leav-ing a written notice at his place of resi-dence, if he be a resident of such county, and if such owner be a non resident of such county, then by leaving the same with the person in charge of such bees, requiring said person, within five days, requiring said person, within five days. Sundays excepted, from the date of said notice, to effectually remove or destroy said hives, together with their entire contents, by burying them or by fire.

Sec. 6. If any person neglects to destroy or cause to be destroyed said hives and their contents in manner as described in section five, after due notification, be shall be desured guilty of a

described in section live, after due non-fication, he shall be deemed guilty of a misdemeanor, and punished by a fine not to exceed fifty dollars for the first offense, and for each additional offense one hundred dollars, at the discretion of the court; and any justice of the peace of the township where said bees exist

of the township where said bees exist shall have jurisdiction thereof.

SEC. 7. The commissioner shall be allowed for services under this act, two dollars for each full day, and one dollar for each half day, the account to be audited by the board of supervisors.

SEC. 8. In all suits and prosecutions under this act, it shall be necessary to prove that said bees were actually diseased or infected with foul brood.

We notice in the telegraphic dispatches from Washington, that the Honse committee on epidemic diseases have agreed to report favorably on the bill authorizing the President to appoint a commission to investigate the adulteration of food and other articles, and appropriating \$20,000 therefor. Slowly, but surely, we are moving on the fortifications of the enemy.

The Marion, Iowa, Register of last week contains the following item upon the subject of food adulteration:

The BEE JOURNAL makes a most happy illustration of the present state of things, by suggesting that if a man tries to pay for counterfeit butter with counterfeit money, he will be at once apprehended and sent to the penitentiary; and that no one would pursue him with deeper wrath than the fellow who was trying to put off the logus who was trying to put off the bogus butter!

Seed Time and Harvest" is the name of a monthly that is sent free to agricultural men. The article on "hot beds" in the January number, is very complete and contains many hints of value to gardeners. It is published by be filed with, and become a part of the Isaac F. Tillinghurst, La Plume, Pa.

#### BEE-KEEPERS INSTRUCTOR.

Importation of Bees,-F. L. Wright, Plainfield, Mich., makes the following very sensible suggestions:

A certain class of bee-keepers are laboring hard to convince the people that the imported queen is the queen; while at the same time another class would have us believe that the imported queen is "good for nix," and that the home-bred is the queen for everybody. One knows that there are black bees

in Italy; another that there are not.

One claims that in Italy queens are reared in a very careless, shiftless man-

reared in a very careless, shiftless manner; another says they are bred in the most careful manner.

Now the question is, Mr. Editor, how are we going to decide which is right and which is wrong? or which are the best and most profitable, the imported or the home-bred? "The proof of the multime is in the eating."

or the home-bred? "The proof of the pudding is in the eating."
Most of us have plenty of imported queens. We also have the light-colored home-bred. Now, when the season opens let us take one or two colonies containing the proof of the pudding the colored home-bred, and set them aside colored home-bred, and set them aside to experiment with. Keep an exact account of all work done with each; the exact number of pounds or ounces of feed fed to each; the exact number of pounds or ounces of comb or founda-tion furnished each; and lastly, the exact amount of honey produced by each, and the condition they are in for

How many will try it? If we experiment faithfully we may perhaps satisfy ourselves, if we cannot convince others f the relative merits of each.

New Races of Bees.-L. H. Pammel, Jr., La Crosse, Wis., writes as follows on the question:

The enthusiast says yes; but the man of prudence says no. Let every bee-keeper for a moment consider the true merits of the races already introduced here. Are they not prolific, good honey gatherers and adapted to our climate? If they fail to gather surplus some seasons, it is either through negligence on the part of the bee-keeper, or from the

some bee-keepers of nature.

Some bee-keepers say: "We want to import a race of bees that will work on red clover." They do not show wisdom by making such wild assertions; for has not nature made ample provision for races of lose that have a shorter for races of bees that have a shorter proboscis, or tongue? Look at the thousands of wild flowers blooming in our forests and meadows, and you can see both the Italian and black bees entering their cavities in search of honey, and filling themselves with the nectar extracted from these beautiful flowers of nature. Look at our large bumble-bees; they are not constructed to become great honey gatherers (al-though they work on the red clover) as they are so large and clumsy that they cannot enter the blossoms with as much cannot enter the blossoms with as much ease as the smaller species of bees; neither do they show such signs of activity; and for these, or some other reasons, are worthless. There are many Asiatic species which I believe have a proboscis large enough for our red clover, but I doubt whether American ingenity will ever hive them, or import them to our shores; neither do I think it desirable, not because I believe the introduction to be of no use. As Wallace says: "No barrier is in the road for them if they want to sting." Such bees I believe would be a missure to us; for no human being would dare to go near them. "Let well enough alone," should be the motto of every beekeeper. Our aim should be to improve those races which have stood the test those races which have stood the test and are warranted to be superior to the common bee. The law of "the survi-val of the fittest," will not improve our

gentle Italians, but through careful selection " we can.

#### DOMINION BAZAAR.

New Bees, -The Editor remarks as follows on this subject:

We suppose that Mr. Jones has called we suppose that Mr. Jones has camed attention to the fact that there are bet-ter bees in other lands, and that others will be induced to look for "new kinds." A clergyman in Asia has discovered a different race of bees there, and soon we may expect to get specimens of the new China Porcelain bees.

The Bee Journal.-The Editor gives the Weekly Bee Journal the following notice :

The American Bee Journal is to hand in its new form. It is now a Weekly, and presents a handsome appearance. We wish it success in the new departure. Standing as it does in the front rank of bee papers we have no doubt it will more than keep up the fair name and fame it has won in the past

#### Southern Michigan Convention.

The Southern Michigan Bee-Keepers Association held their annual meeting at Battle Creek, Feb. 9, 1881. About 30 ladies and gentlemen were present

The subject of foul-brood The subject of foul-brood was discussed, and a resolution manimously adopted, indorsing the action of the committee appointed by the State Bee-Keepers' Convention, to introduce a bill before the Legislature for a law to be passed for the suppression of that dread

disease.

Dr. J. H. Kellogg, of the Sanitarium in Battle Creek, gave an able address on the "Adulteration of Sweets," with experiments; showing that most of the sugars and syrups for sale at the present time, are largely adulterated. He tried an article labeled as "Pure Strained Honey," manufactured in the city of Chicago, and found there was but little honey in it, but plenty of glucose. The meeting adjourned till the first

Monday in May next.
B. Salisbury, Sec.

[The report of the committee, as also the Legislative bill referred to, are in another column, of this paper.—En.]

#### North Eastern Convention.

The eleventh annual meeting of the The eleventh annual meeting of the North-Eastern Bee-Keepers' Association was held at Utica, N. Y., on Feb. 3-5, 1881, President L. C. Root in the chair. After the reading of the minutes, Treasurer Bacon reported the recipts for the year \$93.49, expenditures \$62.21, balance \$31.28.

Mr. T. G. Newman was invited to address the Association, in reply to the

dress the Association, in reply to the resolutions passed at the Convention of last year, which he did. It was then resolved that the subject be entirely dropped, and not again allowed to be brought before the Convention.

A recess was then taken till 7 p. m.

#### EVENING SESSION.

A letter was received from Dr. C. C. Miller, of Marengo, Ill., asking that the association prepare a statistical table of results.

The president said statistical tables

heretofore had been a failure, because only those who had good yields reported. He thought that the interchange of opinion and results in a general way would be better than to make out a table.
Mr. Doolittle said the table heretofore

Mr. Pointtle said the table in retarded had been a failure.

Mr. Knox moved that the statistical table be dropped. This was agreed to without formal action.

A communication from Bingham & Hetherington, asking that their smoker be not entered for premium, was received.

#### Adulteration of Honey.

The following letter on the adulteration of honey was received:

New York, Jan. 31, 1881. Thinking that you may not be aware of the fact that a bill is now before the New York legislature to prevent the adulteration of sugar, syrup and molasses, I have thought proper to write you regarding the matter, and to suggest that your honorable body take immedithat your nonorane body take immediate steps to have the bill amended to include honey also, before it is put on its final passage. The bill was presented by Mr. Root, member from Rochester, by Mr. Root, member from Rochester, and is backed by all the sugar refiners of this city as well as those in other cities, who desire to do an honest busi-ness and have suffered from the evils of adulteration. I am informed by Hon. W. J. Young, who is an ex-member of W. J. Young, who is an ex-member of the legislature, and also a bee-keeper, that there can hardly be a doubt regard-ing the passage of the bill, considering the men who stand backing it, and he thinks the amendment to include honey

so much already, and so far as extracted so much already, and so far as extracted honey is concerned, is in danger of destruction, I hope your president will appoint a committee to confer with Mr. Root and other members interested in Root and other members interested in the bill and secure the amendment. I would suggest that a statement be pre-pared, setting forth the extent and im-portance of the bee-keeping industry, and also of something of the extent of the adulteration of extracted honey, and this latter can see expectly be overesand this latter can scarcely be over-estimated. If you shall succeed with the amendment and the bill passes, you will than has been accomplished by any similar association before on this continent.

On motion the chair appointed the following committee to draft a petition to be presented to the legislature on the subject: Dr.A.H.Marks, Mr.Bacon and Mr. Van Deusen.
At this point quite a number of new

members were received.

#### Foul-Brood.

The secretary read an essay written by W. A. House, of Fayetteville, on the subject of "Foul-Brood," which is given

As the question of foul-brood is again being brought before the public, I deem it my duty to contribute my experience and treatment of this dreaded disease, and treatment of this dreaded disease, hoping it may be of benefit to the experienced bee-keeper as well as the novice. Foul-brood is a disease which attacks the brood, causing it to become a putrid mass, in time destroying the colony, and unless it be given immediate with distillar attacks. and skillful attention, it will make sad havoe among all the bees in that locality. What are the symptoms or means of detecting the disease? Those who have had experience can readily detect it in passing close in front of the hives, by a certain peculiar odor, which is indescribable.

During a scarcity of honey robbers will be almost constantly lurking around the diseased colony, and the bees will appear a little dull or dumpish. The novice would naturally pronounce the colony queenless, but in the hands of a close observing and experienced apiarist close observing and experienced aparist it would at once create a suspicion of foul-brood. On opening the diseased hive you find the sealed brood with sunken caps and a small perforation in the middle, and upon opening these cells with sunken caps you will find a brownish putrid mass, being tough and converged emitting an offensive smell brownish putrid mass, being tough and ropy and emitting an offensive smell. If the brood is found in this state in clusters of a few cells, with cells of healthy brood intervening, the disease is about one-third advanced. The stage of the disease may also be determined by the color of the larvæ. The more advanced the disease, the darker the mass. What are the causes of foul-brood? Some writers claim that this loathsome disease was imported. This cannot be true, for I have known it to cannot be true, for I have known it to exist over thirty-five years ago, or long before the first importation of bees into this country.

As to the first cause of foul-brood. I am unable to give a positive answer, but I am of the opinion that it is owing to a certain state of the atmosphere; the disease attacking a colony that is in a certain unknown condition, the same as the first same as the first case of small-pox is engendered. As soon as a colony is infected with the disease, unless thorough and skillful treatment be rendered at once, it will spread rapidly, attacking the whole apiary, and all the bees in the neighborhood. At this abstraing stage it would apiary, and all the bees in the neighborhood. At this alarming stage it would be almost impossible to eradicate it, as bees in the woods would die with the disease and thus leave an exposure that would last for years. The infection is contagious only by carrying honey, wax, propolis or pollen from the diseased hive. The swarm close by the side of an infected one is no more likely to become diseased, than the one in the farthest diseased, than the one in the farthest corner of the apiary. I know this to be

The disease is spread by robber bees geting into a hive already infected and

constantly; and the first favorable op-portunity offered the robber enters and is almost sure to get enough of the honey to transplant the infection in the parent hive. Soon more bees effect an entrance and finally they make no resistance to the robbers, and many colonies in the apiary become engaged in any interesting the store of the store nies in the apiary become engaged in carrying away the stores, &c., and with them the disease. If any pieces of comb, frames, or any part of the hive, boxes, stand-boards, honey, or in fact any thing pertaining to a hive of foul-brood be exposed for months or even years afterward, the disease will surely be transmitted to your healthy colonies

In many cases the disease is spread by the bee-keeper; who after performing some manipulation of the infected hive. goes to some healthy colony, opens the hive and proceeds to supply their wants without thoroughly washing his hands. The honey, propolis or wax thus con-yeyed from the one hive to the other, has the same effect as though the bees carried it. Then again, while operating with an infected hive, nine times in ten bees from other colonies will get enough honey to convey the disease. This is one cause why those who try experimenting with acids, &c., cannot eradicate the disease from their apiary. As soon as foul-brood is discovered in any hive in the apiary, or with any neighboring chains. hive in the apiary, or with any neighbor-ing colonies, the apiarist should at once stop building up, or exchanging frames with any hives in the yard; as in so do-ing frames of brood or honey may be taken from a colony just attacked, and thus spread the disease very rapidily. A single bee getting one load of honey from the diseased hive, will surely trans-mit the infection to the healthy colony when the work of brood-rearing is in when the work of brood-rearing is in

If the disease should break out in a very few hives only, I would advise, by all means, the immediate destruction of the hives and contents, by burning them as soon as discovered. The boxes, to the hive at the time should also be burned. This is undoubtedly the only burned. This is undoubtent the only safe and sure remedy for the novice or inexperienced. In fact it would be the most available means of eradicating the disease with an experienced apiarist, when the infection is discovered before when the infection is discovered before an exposure to the remaining colonies, but if healthy colonies have come in contact with the honey, pollen, propolis or wax of an infected hive the skillful or experienced apiarist can save his bees and honey by carefully adhering to the following mode of treatment; Remove the colonies to a close and darkened room. Shake the bees of each hive into an empty box that is new and clean. Let them remain there and clean. Let them remain there until they show signs of stupidity, when they will have consumed all the honey they carry with them. Now take the bees out of the box and put them into a new clean hive filled with foundation, and them with sugar syrup, or honey feed them with sugar syrup, or honey that you know is not from a diseased hive: or, if it be in time of season when honey is coming in they will gather from the fields to supply their wants the same as a young swarm.

The honey may be extracted from the infected hive, but the utmost care must mtected hive, but the utmost care must be taken not to expose a single drop of the honey, comb, or any part of the hive, where the bees can get it. The honey should be brought to a boiling heat and then sold to some manufacturer, so that it will not find its way back to the bees. Some writers claim that the wax also may be extracted and made into foundation. I have had no made into foundation. I have had no experience in this line, therefore cannot give positive advice; but I should immediately burn the hives, frames, bottom-boards, boxes and everything pertaining to the infected hive.

My experience with foul-brood dates back to 1845. My largest experience, however, was between 1850 and 1860, when the disease raged through Montwhen the disease larged though wonly gomery county and eastern and central New York. Through the ignorance of a neighboring bee-keeper I had one or two cases in 1867. Since that date there either of my apiaries, neither has there been a case of this disease with have been no signs of foul-brood in ing the passage of the bill, considering the men who stand backing it, and he carrying honey, pollen, propolis, wax or would be readily accepted. In view of the fact that our industry has suffered hurking around a diseased colony almost. By the fact that our industry has suffered hurking around a diseased colony almost.

Mr. House said further that the great danger was in leaving the diseased honey exposed where other bees could get at it. His experience had been much like that of Mr. Quinby. In the fall he had several dozen cells attacked. In the spring he would drive the bees out, provided the colony was strong enough. In his article he had put the worst side out, in order to put men on

worst side out, in order to put men on their guard.

F. H. Cyrenus said he would not burn a hive, or destroy all the comb. He would give the bees a new hive and clean cells. He would not be afraid to give them back the same honey after it had been scalded.

Mr. Betsinger asked if he would use any of the combs connected with the foul-brood colony.

Mr. Cyrenus said he would if the cells Mr. Cyrenns sand he would it the cens were empty, containing absolutely no honey or brood.

Mr. House said it was dangerous to use such combs.

Mr. Cyrenns said a man might have

Mr. Cyrenns said a man might have 50 valuable hives, which it would uot do to burn. It would be better to scald the hives.

Mr. Honse said be had known an in-

fected bottom-board to transmit the infection after it had been exposed during all of the winter months. There were two stages in the disease, the last

proving fatal. proving fatal.

Mr. Rians said he had had experience with foul-brood. In one case there were but three cells, which he cut out with his knife. In the case of two other colonies where the disease had progressed too far, he destroyed the comb and extracted the hone. He made new tracted the honey. He made new colonies out of the old ones, and they were healthy. The honey which he had extracted, he boiled until it almost boiled over. He fed it out, and soon found ten or a dozen colonies affected. Where practicable he cut out the foul Where practicable he cut out the foul cells. In this way he reduced the disease, until now he had but 3 colonies affected. He was not aware that there were other hives in the neighborhood affected, and to which his bees had access.

Mr. Cyrenus said perhaps his bees got the infection elsewhere, and did not get

it from the honey.

Mr. Bacon said 40 years ago he lost 60

Mr. Bacon said 40 years ago he lost 60 colonies from foul-brood. Sometimes young bees died in the comb, and this was mistaken for foul-brood. He had had no foul-brood in 30 years.

Mr. House said in Mr. Rian's case his bees were not affected with genuine foul-brood. If not, it would have proved more destructive. He could detect foul-brood by the odor. detect foul-brood by the odor.

Dr. Marks said he had had foul-brood but had sold the bees. With other bees the disease disappeared without treat-

Mr. Doolittle instanced a case of foulbrood where the bees all died. He once had 5 colonies diseased out of 14. He put these colonies in the cellar in the fall. In the spring he found that nearly all his bees had foul-brood, he believed because they had been wintered together. He let such bees as would, swarm, putting them in new hives. He kept the old hives for a year or so and then used them again. He did not believe hives would carry the contagion after having been expessed for a winter after having been exposed for a winter. He did believe the contagion would spread, by putting the bees together in the cellar.

Mr. House said the danger in this case

was the honey the bees had taken from a diseased colony.

Mr. Betsinger said but very few per-Arr. Betsinger said but very few persons knew what foul-brood was. It was a very dangerous disease, one of the most dangerous in the apiary. Foul-brood will present itself often in a very bad state, at times, and will become dormant of itself, and then burst forth versity with all the destructiveness of again with all the destructiveness of small-pox. Foul-brood can never be cured. We do not know the cause. I have attempted to wipe it out and thought I had succeeded, but I had not. thought I had succeeded, but I had not. I know that any portion of honey, comb, or pollen affected with the contagion will transmit it. Dry combs would transmit it. He did not believe there was one apiary in a hundred that did not have foul-brood. Italian bees would drag out foul-brood. If a hive had foul-brood in the spring, it would

different stages.

Mr. House said that one year of foul-brood would use up the colony. With Italian bees he had known it to break out again in the spring.

Mr. Betsinger said a bee-paper had stated that in case of foul-brood, if the bees were shaken off on foundation, the disease would be cured. Experience had proved that this was not true.

The president said the fact that foul-brood had prevailed before 1870, proved that it was liable to appear again. In 1869 in one of his apharies, out of 100 colonies one was affected with foul-brood in the spring. In the fall all but 4 of the colonies had it, caused by the other bees robbing the affected brood. He did not think the plan recommended by Mr. Rians safe. If a hive has been or is diseased, he would proceed as Mr. House advises, putting them on new foundation. He believed freezing or scalding the hives would make them safe. He had also found it safe to feed the honey after it had been scalded. He would certainly not winter a diseased colony. His experience went to prove would certainly not winter a diseased colony. His experience went to prove Mr. Cyrenus' statement in regard to combs. He had hung up combs during the winter where they were frozen hard. Used them again in the spring, and the disease disappeared. He should not, however, advise the use of combs in this way

Mr. Betsinger said you can put it down as a fact: No honey, plenty of foul-brood; plenty of honey, no foul-brood. In 1869 the honey season was prood. In 1869 the noney season was poor, and we had plenty of foul-brood. I lost 300 colonies that season. In 1870 the honey season was good, we had no foul-brood. Plenty of honey crowds out

The president to W. E. Clark—1 do not think freezing honey would remove the contagion. Scald the honey and the

hive. Freeze the comb.

Mr. Rians asked Mr. Betsinger his theory of honey crowding out foul-

Mr. Betsinger said honey and foul-brood could not occupy the same space at the same time.

Mr. Doolittle said he should destroy a

Mr. Doolittle said he should destroy a hive if only a single cell was affected. Where the cells were of a grayish color he did not believe the case to be genuine foul-brood. In the latter case, the cells were a stringy putrid mass. The dead bees would not be carried out. He

offered the following:

Resolved, That this Convention believes that foul-brood is a very dangerous disease, and that we advise all to be careful in experimenting in regard to its cure. If but two or three colonies are affected in any apiary, destroy hives, combs, and all.

Mr. Betsinger spoke of a case where one-fourth of the entire apiary was made up of dead larvæ foul-brood. He Italianized the apiary, and the bees carried out the larvæ. The man had the same number of colonies to-day, not having lost a colony.

Mr. Doolittle said in case of foul-brood, the larvæ lay in the cell after being sealed. It assumed a brownish color, became salvy, and very offensive to the smell.

All agreed that this was a correct description of foul-brood. Mr. Betsinger spoke of a case where

All agreed that this was a correct description of foul-brood.

The president said the colonies could be saved without destroying the hives and hees. If 50 or 100 colonies could be saved by any other method than destruction, he thought the same mode of treatment should hold good in the case of one or two colonies.

Mr. Doolittle said his advice was for the novice or inexperienced bee-keeper, and for experienced men as well. He thought it better to destroy two or three hives, than to run the risk of having any foul-brood in the future. In the case of 50 or 100 colonies the cost was too great. Mr. Doolittle's resolution was unanimously adopted.

#### MORNING SESSION.

By unanimous vote, Mr. T. G. New-

Adjourned to 1:30 p. m.

#### AFTERNOON SESSION.

Mr. J. J. Jones, of Trenton, was made an honorary member.

The election of officers for the ensuing

The election of officers for the ensuing year resulted as follows:

President—Dr. A. H. Marks; l'ice
President—G. M. Doolittle; Secretary—Geo. W. House; President—R. Bacon.

Utica was selected as the next place of meeting, and the last Wednesday in January as the time.

The retiring President, Mr. L. C. Root, then read his annual address, for which he was given a vote of thanks.

which he was given a vote of thanks.

The committee on adulteration of honey reported the following:

Whereas, the adulteration of extracted

thereas, the adulteration of extracted honey is very largely practiced by unprincipled dealers and adulterators, and threatens to almost destroy the pursuit of honey production; and as a bill is now before the legislature of New York to prevent the adulteration of sugars, syrups and molasses, and as the adulterations of honey are just as detri-mental to the public as they are to honey

producers: therefore,

Resolved, That our president be directed to cummunicate with Mr. Root, member of the legislature from Rochester, N. Y., having the bill in charge, and that he present these resolutions and use his influence with that gentleand use his influence with that gentleman to have honey included in that bill before it is put upon its final passage, and that all kee-keepers in this state who have any influence with members of the legislature, are requested to write them at once and ask their influence in favor of the bill.

Resolutions unanimously a legislature and the second that the second

Resolutions unanimously adopted.

#### MARKETING HONEY.

The secretary read an essay on the subject of marketing honey, written by C. P. Dadant, of Hamilton, Ills.
J. H. Nellis read an essay on the same subject, written by L. M. Wainwright, of Noblesville, Ind.
The Secretary, George W. House, read his article on the same subject.
T. G. Newnan, of Chicago, spoke on the subject. It was one of the most important known to bee-keepers. A misthe subject. It was one of the most important known to bee-keepers. A mistake of one cent per pound on the price of honey is a mistake of \$750,000 on the annual production of the honey crop of the United States. Comb honey must be made attractive, Honey is a good medicine. We must make this known. He made a pleasant speech which put the convention in good humor. In reply to a question from Mr. Bacon, the speaker said glucose was made in Chicago very largely, and was used in adulterating everything eatable that could be adulterated by it. Glucose is driving honey out of the market, and beekeepers must protect themselves. Illikeepers must protect themselves. Illinois glucose makers are opposing the efforts of the bee-keepers, by corrupting the members of the legislature; the same thing may be done in New York. Did you ever stop to think that you can buy the finest golden drips and silver drips syrups for less money than the commonest molasses that is pure is worth? The explanation is "glucose." The association, in order to secure the passage of the anti-adulteration bill, should send a representative to Albany armed with the signatures of its members, Glucose is the essence of rags and keepers must protect themselves. bers, Glucose is the essence of rags and refuse matter from cities, worked up

with corn syrup.

J. H. Nellis said just as soon as honey sold for the same price as canned sweets, the market would never be overstocked. man, of Chicago, editor of the American Solution the same price as canned sweets, the market would never be overstocked. He exhibition of aparian the previous day, and the reception of the Association.

Root, is hereby appointed a committee to wait upon your honorable body for the purpose of the discussion will think the series and the discussion will be series and the discussion will be published hereafter.—Ed.]

Adjourned to 1:30 p. m. the wholesale adulteration of all sweets, which not only ruins the prospects of legitimate business, but which is destructive to the health of the consumers.

The resolution was adopted.

Mr. Nellis moved that the association The resonance...
Mr. Nellis moved that the association pay Mr. Root's expenses to Albany to favor the anti-adulteration bill.
Mr. Bacon moved that Mr. Nellis act as alternate. Appointed.
Adjourned till 7 p. m.

#### EVENING SESSION.

At the opening of the evening session the following telegram from D. A. Jones, at Beeton, Ont., was read:
"My eyes are no better, and I cannot send the essay. My bees are wintering finely; the holy bees the best. Accept my congratulations."

my congratulations." Essays on the subject of "Apiarian sup-plies and the queen trade," written by A. B. Weed, of Detroit, and the "Great Revolution," written by A. Webster, of East Roxbury, were read by the secre-

Vice President Doolittle presided, the president, Dr. Marks, having been called home.

Mr. Betsinger asked: "What constitutes an average yield of honey, both comband extracted, in the United States." and Canadas east of the Rocky mountains." Some say they have had a good tains." Some say they have had a good season, 40 pounds to the colony; others say they have had a good season, 25 pounds to the colony; others say they have had a poor season, 100 pounds to the colony. What he desired was to fix the standard yield. The question was important as showing the entire yield of the country.

Mr. Yayman questioned Mr. Betsin-

Mr. Newman questioned Mr. Betsinger, who replied that about 50 lbs. comb ger, who replied that about 50 lbs. comb honey and 80 lbs. extracted honey per colony was a standard yield, in his opinion. If this association did not fix the standard, no other association would. Mr. Root said each bee-keeper would have a standard of his own.

Mr. Newman was glad the subject had been brought up, although it would be bard to settle.

hard to settle.

The president said the Association had adopted a standard for a colony of bees, but the action amounted to no-

thing.

Mr. Root said the papers reported in some states half a crop, in others an average yield, etc. The question was, what did the papers judge from in making an estimate?

mg an estimate?
Mr. Bacon said the yield in Kentucky
could not be compared with New York,
or New York with Canada.
Mr. Newman said he had stated in the

Aff. Newman said he had saided in the national convention that the yield for 1880 throughout the United States, was but a half a crop. He had, by patient toil, arrived at this conclusion. It was well known that he had called for reports of his subscribers in the different states and many handsale of these restates, and many hundreds of these re-ports he had summarized, in order to

ports he had summarized, in order to arrive at his conclusion.

Mr. Bacon said he had looked around in his vicinity, and concluded he had but one-third of a crop, and had so reported to Mr. Newman. But late in August and early in September his bees worked very hard, gathering honey from seladine. He found that Mr. Root had a better yield than he, even with selandine.

Mr. Newman said he could not judge by the opinion of bee-keepers whether

their yields were good or bad, except by the number of pounds per colony. W. E. Clark moved that in future the question drawer be opened on the after-noon of the second day, instead of the

third day; carried.

An adjournment was then taken for the exhibition of aparian supplies, after which adjourned to 9 a. m.

[The third days' proceedings will be

# Books for Bee-Keepers.

Cook's Mannal of the Aplary, -Entirely rewritten, greatly enlarged and clegantly illustrated, and is fully up with the times on every conceivable subject that interests the aplarist. It is not only instructive, but intensely interesting and thoroughly practical. The book is a masterly praduction, and one that no bee-keeper, however limited his means, can afford to do without. Cloth, \$1.25; paper covers, \$1.00, postpuld. Per dozen, by express, cloth, \$12; paper, \$9.50.

Anishy's New Bee-Keeping by L. C. Ront.
The mither has treated the subject of bee-keeping han manner that cannot full to interest all. Its style is plain and forelible, making all its renders sensible of the fact that the author is really the master of the subject. Pice, \$1.50.

Novice's A BC of Ree-Culture, by A. I. Root. This embraces "everything pertaining to the care of the honey-bee," and is valuable to beginners and those more advanced. Cloth, \$1,25; paper, \$1.00.

King. Hee-Keepers' Text-Book, by A. J. King.—This edition is revised and brought down to the present time. Cloth, \$1.00; paper, 75c.

Laugstroth on the Hive and Honey Bee This is a standard scientific work. Price, \$2.00.

Blessed Bees, by John Allen.—A romance of bee-keeping, full of practical information and con-tagious enthusiasm. Cloth, \$1.00.

Beec'ntimes or Successful Management of the Apiary, by Thomas G. Newman.—This pamping temperature of the Apiary. By Thomas G. Newman.—This pamping temperature is the following subjects: The Location of the Apiary—Honey Plants, once nearning—Feeding—Swarming—Dividing—Transfer—Onitarions—Introducing Queens—Extractic—Onitarions—Introducing Queens—Extractic—Onitarion of Preparing Honey for Market, etc. It is published in English and German. Price for either edition, 40 cents, postpaid, or \$5.00 per dozen.

Food Mallferalion; What we eat and should not eat. This book should be in every family, where it ought to create a sentiment against the adulteration of food products, and demand a law to protect consumers against the many health-destroying adulterations offered as food. 200 pages. Paper, 50c.

The Dzierzon Theory; -presents the fundamental principles of bee-culture, and furnishes a condensed statement of the facts and arguments by which they are demonstrated. Price, 15 cents.

which they are demonstrated. Price, 15 cents.

Honey, as Foot and Medicine, by Thomas o. Newman.—This is a pamphlet of 24 pages, discoursing upon the Ancient History of Bees and Honey; the nature, quality, sources, and preparation of Honey for the Mirket; Honey as an article of food, giving recipes for making Honey Cakes, Cookies, Puddings, Foam, Wines, &c.; and Honey as Medicine, followed by many useful Recipes. It is intended for consumers, and should be scattered by thousands all over the country, and thus assist in creating a demand for honey. Published in English and German. Price for either edition, 6c.; per dozen, 50c.

Wintering Bees.—This pamphlet contains all the Prize Essays on this important subject, that were read before the Centennial Bees-Keepers' Associa-tion. The Prize -\$25 in gold—was awarded to Prof. Cook's Essay, which is given in full. Price, 10c.

Bees and their Management. This pamphlet was issued by the Italian Bee Company, and has had a large circulation. The price has been reduced from 20 cents to 10 cents.

The Hive I Use—Being a description of the hive used by G. M. Doolittle. Price, 5c.

Kendall's Horse Book—No book can be more useful to horse owners. It has 35 engravings, illustrating positions of sick hoses, and treats all diseases in a plain and comprehensive manner. It has a large number of good recipes, a table of doses, and much other valuable horse information. Paper, 25c.

Chicken Chotera, by A. J. Hill,—A treatise on its cause, symptoms and cure. Price, 25c.

Moore's Universal Assistant contains information on every conceivable subject, as well as respirs for almost everything that could be desired. We doubt if any one could be induced to do without t, after having spent a few hours in looking it brough. It contains 480 pages, and 500 engravings, loth, \$2.50.

Ropp's Easy Calculator.—These are handy tables for all kinds of merchandise and interest. It is really a lightning calculator, nicely bound, with slate and pocket for papers. In cloth, \$1.00; Morocco, \$1.50. Cheap edition, without slate, 50c.

#### SPECIAL NOTICES.

Premiums.—For a club of 2, weekly PREMIUMS.—For a club of 2, weekly we will give a copy of "Bee-Culture;" for a club of 5, weekly, we will give a copy of "Cook's Manual," bound in cloth; for a club of 6, we give a copy of the Journal for a year free. Do not forget that it will pay to devote a few hours to the BEE JOURNAL.

"What is the meaning of 'Dec. 181° after my name on the direction-label of my paper?" This question has been asked by several, and to save answering each one, let us here say: It answering each one, let us here say: It means that you have paid for the fall year, or until "Dec. 31, 1881." "June 81" means that the first half of the year is paid for, up to "July 18t." Any other month, the same.

It would save as much trouble, if all would be particular to give their P.O. address and name, when writing to this office. We have several letters (some inclosing money) that have no name. Many others having no Postoffice, County or State. Also, it you live near one postoffice and get your mail at another, be sure to give the address we have on our list.

When changing a postolice address, mention the *old* address as well as the new one.

© Constitutions and By-Laws for local Associations \$2 per 100. The name of the Association printed in the blanks for 50 cents extra.

a satisfactory nature.

We will send sample copies to any who feel disposed to make up clubs for 1881. There are persons keeping bees in every neighborhood who would be benefitted by reading the JOURNAL, and by using a little of the personal influence progressed by about every one. fluence possessed by almost every one, a club can be gotten up in every neighborhood in America. Farmers have had large crops, high prices, and a good demand for all the products of the farm, therefore can well afford to add the BEE JOURNAL to their list of papers for 1881.

We have filled orders for quite a number of Binders for the Weekly BEE JOURNAL. We put the price low, 30 per cent. less than any one else could afford to sell them, for we get them by the quantity at wholesale and sell them at just enough to cover the cost and postage, the latter being 21 to 23 cents, on each. We do this to induce as many as possible to get them and preserve on each. We do this to induce as many as possible to get them, and preserve their Weekly numbers. They are exceedingly convenient; the JOURNAL being always bound and handy for reference. The directions for binding are sent with each one.

BEE JOURNAL will be sent free to any names that may be sent in. Any one intending to get up a club can have sample copies sent to the persons they desire to interview. desire to interview, by sending the names to this office.

Instead of sending silver money in letters, procure 1, 2 or 3 cent stamps. We can use them, and it is safer to send such than silver.

#### Sting of the Honey Bee.

Before we import the stingless bees, or the great bee of Java, Apis dorsata, with its immense stinging power, let us consider the sting of the bees we now have, as set forth in the following article by Mr. Bledsoe, of Natches, Miss.:

The bee sting, in the first place, is not a perfect tube, nor does it work with a telescope motion, strictly speaking. It

Bee Sting magnified, showing the barbs.

is a complex instrument, being composed of three distinct parts, of which the sheath forms one. These three parts join near the edges, and form a tube which, viewed sectionally, has the shape of a triangle, the angles being rounded off

The sheath near its point is narrow, the sheath, and along which the parts but grows wider towards its base, where it gradually embraces the remaining tapers down to an exceedingly fine point. Near the point begin the barbs, which their working. Near each edge of the inner or hollow side of the sheath, runs a ridge which fits a corresponding groove in each of the other parts. Near its point, which is rounded rather bluntly, it is armed with two feeble sets of barbs, numbering as many as four in each set.

The sheath near its point is narrow, the sheath, and along which the parts ut grows wider towards its base, where gradually embraces the remaining tapers down to an exceedingly tine point. Near the point begin the barbs, which in some stings number as many as ten,

Sectional View of a Bee Sting

apart from the base of the sting. The poison readily passes along the tube (which is a continuation of the cavity), and finds its way into the wound with

and finds its way into the wound with great facility, owing to the peculiar formation of the sting.

It may often happen that one or both of the chief parts of the sting are left in the wound when the sheath is withdrawn, but are rarely perceived on acacount of their minuteness, the person stung at the same time congratulation stung at the same time congratulating himself at the same time that the sting has been extracted.

For the American Bee Journal.

#### A Scrap of History on Importing Bees.

#### C. J. ROBINSON.

When the AMERICAN BEE JOURNAL was first published in Philadelphia by A. M. Spangler & Co., I commenced to scan its 24 pages, but have not been a constant reader ever since its first issue, January, 1861. I have not seen a historical account of the introduction of the Ligurian or Italian Alps Bees into this country, published in the said Journal. Statements by several writers have appeared in different periodicals concerning the first introduction of the Orienpeared in different periodicals concerning the first introduction of the Oriental bees, but the several stories do not agree as to date, incidents, nor as to who was the first successful importer. A correspondent of the New England Homestead claimed that Mr. Cary, Coleraine, Mass., took charge of the first Italian bees ever imported that were made to live, and that "Mr. Parsons, of Flushing, Long Island," was the importer, and gives the date of the first importation in 1860. If the reader will refer to the first numbers of the AMERICANTER. ter, and gives the date of the first importation in 1860. If the reader will refer to the first numbers of the American can be Journal he will learn from Mr.P.J. Mahan's advertisement that he, Mr. Mahan, was the first to land the Italian bees on the American continent in September, 1859. Other parties who imported bees advertised in the American continent in September, 1859. Other parties who imported bees advertised in the American Can Bee Journal at the same time, but none of them disputed Mr. Mahan's claim except Mr. Wm. Rose, of N. Y. City, who contradicted a statement I had made in an article in the Country Gentleman, crediting Mr. H. with the honor of being the first successful importer of bees. In a subsequent communication from Mr. Rose, published in the Country Gentleman, he admitted that he was not aware that Mr. H. brought over bees at the same time of the Sheath, is attached a plano-convex valve, the convexity of which is adapted to the inner side of this receptacle, and they occupy about one-half of the space therein. When the sting is in action, each of the chief parts is thrust out and withdrawn alternately; so that when working its way into a

## THE STING OF THE HONEY BEE.

VERY HIGHLY MAGNIFIED.

The whole Bee Sting, magnified. Point of Sting, highly magnified.

The base of the sheath or sting is large, being broad and somewhat flattened, with an oblong hollow, which constitutes a receptacle for the poison just previous to injection in the wound.

The other two parts constitute the sting proper, and in a sectional view are sting proper, and in a sectional view are semi-circular, the upper edges being thicker than the lower ones, and squared to each other, one of the edges having a projection extending along the under or inner portion of it, thereby forming a rabbet along which the opposite part freely moves. The under or inner edge of each of these parts tapers down to extreme thinness, while near the termination of the edge there runs a minute groove which corresponds with the ridge mentioned in the description of

introduced into Germany. Madame de Padua, of Mira, Italy, wrote to the the celebrated Rev. Mr. Dzierzon, who resided in Lower Sileria, for a model of his bee hives, and she sent him a colony of the yellow-barred race of bees, which were the first ever seen in that part of Europe. (The Italian hives were about 4 feet long by 1 foot broad and deep, composed of half inch boards, and one end entirely open for the entrance

In 1856 Mr. Samuel Wagner, of York, in 1856 Mr. Samuel Wagner, of York, Pa., attempted to import a few colonies of Italian bees, but they all perished on the voyage. Mr. Langstroth was in error when he wrote in his book that "Mr. Wagner and Mr. Richard Colvin, of Baltimore, imported bees in 1859." It was in 1860 when Messrs, Wagner and Colvin first succeeded in importing the Colvin first succeeded in importing the ellow-barred bees, and they were from Mr. Dzierzon's apiary.

The history of the first successful importation of those yellow bees into this country dates back to the summer of 1859, when our Government was petitioned, by a bill introduced in Congress, to import camels and Cashmere goats for domestication in the South. At that time Mr. P. J. Mahan solicited an order from the then Commissioner of the U. S. Patent Office, to purchase a few colonies of the European bees for the Department of Agriculture (then under the jurisdiction of the said Commissioner), and thus get that breed of honey bees introduced into this country by the fostering aid of our government. Mr. Mahan was not a throne "stalwart," and his petition was denied. Just at that his petition was defined. Just at that time the said Commissioner sent Mr. T. B. Parsons, of Flushing, N. Y., who was a botanist and nurseryman, on a professional tour through Europe for the purpose of making a report to said Department. (See its report for 1860 or Department. (See its report for 1860 or 1861). Mr. Parsons was not an apiarist, but the Commissioner authorized him to purchase ten colonies of Italian bees on government account. Mr. Mahan proceeded to import bees on his own ac-count, and visited Europe with a view of purchasing a few colonies of Dr. Dzierzon, and attending to them during the whole voyage. Mr. Parsons reported that he experienced dangerous difficulties in making his tour through Italy, as war was then going on, but he claimed as war was then going on, but he canned to have purchased ten colonies on his government order, and ten colonies on his individual account. The sequel to this enterprise clearly indicates the character of public servants—service and jobbery. Thus the bees purchased by Mr. Parsons were all shipped on board. by Mr. Parsons were all shipped on board the same vessel with the bees purchasof the bees during their voyage across the Atlantic. When the ship arrived in the Atlantic. When the ship arrived in the N. Y. harbor a strife sprung up, as is usual, between the parties of New York and the Philadelphians, the New York party being anxious to gain the honor of priority, and the Philadelphi-ans ambitious to secure the same honor.

Both parties endeavored by stratagem, to win their point, and a hive of the Parsons bees was put into the hands of a stout stalwart New Yorker, and a hive of Mahan's bees were put into the hands of a strong active Philadelphian. The point was to get priority of landing those bees on American soil. Well, when the boat from the steamer neared the dock, the New Yorker swung and threw the hive of Parson's bees on to the wharf, where it was smashed by the col-lision, and so won; as the boat touched, the Philadelphian ran with the bees he had in charge and placed them safely on land. Thus Mr. Mahan was the quastatore or pioneer importer of Italian bees into America.

Now the reader is wanting to know

what became of the bees purchased for and with the government funds. Well, Parsons claimed and took all of the colonies that survived the voyage. Of course it was the Government's bees that died *en route*.

Mr. Mahan got information that the

bees purchased by Parsons cost our government \$1,800, but when I quizzed the Commissioner on that matter, he said the cost was not one-half that amount, and he seemed to be entirely satisfied with the case as it stood.

At some future time 1 may write you more on this subject.
Richford, N. Y., Jan. 23, 1881.

Nor the American Ree Journal.

#### The Price of Success.

WM, F. CLARKE.

Success is always more or less costly. The example of a successful man always fires the ambition of others, but few count the cost of success. Just now, eount the cost of success. Just now we have, here in Canada, a large number of persons who aspire to be Joneses in the line of bee-keeping, and the mischief is, they fancy they can do it all at once. They forget that this man has kept bees from boyhood; that he has laboriously and slowly plodded his way up to his present eminence; and that it is to his present eminence; and that it is only quite recently that he has attained distinguished success. There is no magic or charm about bee-keeping. The "mysteries" are open secrets. But there is a certain knack; a species of apicultural talent, a genius or ability, resulting from a combination of natural qualities and long experience, which makes one man succeed where others fail. It is thus in every walk of life. Statistics prove that only one merchant in 27 succeeds in trade. Girards and Stewarts are mighty scarce in the haunts of commerce; quite as much so as Grinms and Hetheringtons are in the realm of apiculture. There are numerrealm of apiculture. There are numerous instances of failure in every line of human occupation. The man who wins success, does so by dint of those faculties and methods which command it. Bee-keeping is no exception to this general rule. There is no royal road to apiarian success: rather there is only the royal road, which is paved with intelligence, patience, and resolute determination.

Listowell, Ont., Feb. 15, 1881.

Queen Rearing.—I see, on page 35 of he weekly BEE JOURNAL, that Mr. W. 2. Hutchinson states that he has "made \$25 per colony this season rearing dollar queens." He then says, "let us hear lar queens. from breeders of high-priced queens, if they have made more." It would be interesting, I think, to the readers of the JOURNAL, to know how many colonies were made to yield this amount; as nies were made to yield this amount; as it would go to show how many can be made to yield so large a profit when under the care of one man. Mr. Hutchinson does not state whether or not the time of the nuclei is counted, in which the young queens must have been reared and kept until sold. My own aim has always been to sell that which was thoroughly tested and I knew to be good, wither them that which is low wireld and to the counter of the control of th rather than that which is low priced and doubtful. If Mr. H. can show that \$25 per colony can be made from an unlimited number of colonies, then he will certainly be acknowledged as the most successful of bee-keepers.

A. B. WEED. Detroit, Mich.

The Shaking-Off Process.—In answer to your request in the Weekly of the 9th inst. we would say, that the article referred to is to be found on page 255, instead of 355, 1879, under the heading. "Management during June." As it would only take time and space to repeat Mr. Doolittle's plan in detail (for this would be the best we could do) we will only say that by the sheking of process. only say that by the shaking-off process we mean the artificial nerease of one swarm from every two old colonies, by shaking the bees from the combs of the first hive, and placing these combs with a new queen on the stand of the second, this latter being removed to a new location. We have been successful to a great measure in handling bees in this way, and can recommend it as worthy of trial. Like many others, we, too, can help swell the chorus in favor of the young Weekly. At first it did not seem to fill the place of the attractive appearance and enveryment the state. anee and convenient shape of the old monthly; but after a month's trial we find the weekly visits amply compensate for all deficiencies in other respects, especially since the new feature of its being cut and pasted made its appear-ance. The Weekly deserves the sup-

port of all bee-keepers. Our bees had a joyful time last week. Since the first part of November they had been con-Since the first fined to their hives without interruption, and we feared bad results; but the way they made the air buzz on Wednesday last, and their present condition, does not indicate anything very serious as yet. Of the 82 colonies at our home apiary, we have lost so far but 1; the We winter rest seemed to be all right. on summer stands, and use a 4-inch chaff cushion for protection on top, contracting the brood-chamber with chaff division boards. Greiner Bros. Naples, N. Y., Feb. 14, 1881.

[The explanation above referred to is in answer to an inquiry from Mr. C. Wurster, in the Weekly BEE JOURNAL of Feb. 9th. Messrs. Greiner Bros. will accept our thanks, as also congratulations on the happy condition of the bees in their home apiary.—ED.]

Referring to the article of Messrs. Greiner Bros., "Prevention of Swarming," in American Ber Journal of Jan. 19, 1881, I would like to inquire: 1. What is the "shaking-off process"? 2. Does it mean the reduction of the number of the formal of the swarm. ber of bees of a colony likely to swarm by shaking them off of the frames, addoy snaking them on of the frames, auc-ing them to a nucleus or weak colony? 3. If so, how is best to guard against shaking the queen off into the live of the weak colony? I so far find it a tedious job to find the queens.

BEGINNER. Grand Island, Neb., Feb. 7, 1881.

[The process referred to is described above. It will be economy to Italianize your bees, if for no other purpose than convenience in finding queens.—En.]

Had a Good Flight .- We had a thaw during last week, with fogs, mist, and a heavy rain on the 12th, which carried off most of the snow in a flood. Frioff most of the show in a hood. First day, the 11th, was clear and warm—a fine day for the bees to fly, and they in-proved it. too; every colony, and 4 that were nothing but strong nuclei last fall. carried out a good many dead bees during the day; but there are many live ones left yet. They appear all right. This is the first flight since about the middle of November.

R. Downs. middle of November. R. Down Naugatuck, Conn., Feb. 15, 1881.

Bees doing Well.—I started to winter 30 colonies, all in chaff hives, and have 27 remaining at this date. Of those 27 remaining at this date. Of those which I have lost, 2 starved and the other was diseased, I think. The percentage of loss among bee-keepers in this section has been even less than mine, where chaff hives were used; in mine, where chaff hives were usen; mingle-walled hives it has been greater, with a prospect of more loss. The recent heavy thaw has enabled my bees to take a good fly. They came out largely for 3 days in succession, and but few were lost. I am much pleased with the Weekly JOURNAL. C. M. BEAN. the Weekly Journal. C. M. Bean McGrawville, N. Y., Feb. 14, 1881.

Bees—Present Condition.—In looking over 43 colonies to-day (all the hives at the home apiary) I find them as follows: 4 dead, 6 weak, 12 fair, 13 prime, 8 extra, and 7 with a little brood. Doubtless more had brood, but I did not see any more in the sweepings of the bottom hoards. Fair, prime and extra are my marks for good, better, best.

II. T. COLLINS.
Jacksonville, III., Feb. 8, 1881. -Present Condition.—In looking

The Dying and the Dead.—Many bees have been lost hereabouts by the severity of the winter following a season of rery scant supply of honey in the flowers. I increased to 25 from 8 colonies, and although 1 fed a barrel of honey in the autumn, 10 are now dead. All are out-doors.

1. T. Scofield. out-doors. Barnesville, ().

Bees all Alive.—The thermometer indicates 15° below zero this morning—the deates 15-below zero this morning—the coldest we have had this winter. My bees are all alive yet. The bottom boards of my Quinby chaff hives are dry. I am in good hopes for the future.

W. BOLLING.
Dunkirk, N. Y., Feb. 3, 1881.

The Season in Florida.—On Dec. 28, I left home for a trip through Florida, where I saw many things that were new and interesting. Florida is a country peculiar to itself. There is no other like it. The morning I left Charlestop, the theory of the through the standard of the same of like it. The morning I left Charleston, Dec. 30, the thermometer stood at 12-above zero, and when next day, I entered the northern part of Florida, I found the oranges all frozen, and grave fears entertained for the trees, many of which were killed. About Gainesville the orange trees shed their leaves, and the lemon trees were mostly killed. the lemon trees were mostly killed. At Ocala, I found the orange trees unburt, but in many places the lemon trees were killed, and the lime and guava trees at Gainesville were killed. From Ocala south, as far as Fort Mead and Tampa, the orange trees looked lovely. At Fort Mead and Tampa not only the lemonth of the lambar of the lemonth of the lemont on, but the lime and guava were in fruit and in bloom at the same time. fruit and in bloom at the same time. Tomatoes were in bloom and had ripe fruit, of which I ate. Think of this, Mr. Editor, while you were many degrees below zero.

J. W. Hudson, M. D. Mayesville, Fla., Feb. 6, 1881.

Bees Leaving their Hives.—I must confess that I am very much pleased with the Weekly Bee Journal, and read each number carefully. Success to it and its editor. Will some one inform me why my bees persist in coming out of their hives when the weather is so cold? Yesterday was a bright sun-shiny day, but very cold all day, yet my so cold? Yesterday was a bright sunshiny day, but very cold all day, yet my bees came out in great numbers, never to return to their hives, as the weather was so cold they would drop in the snow and perish. I put my bees into winter quarters the first of November, using chaff division boards made after Mr. A. I. Root's plan. For the top or cover of my hives (after reducing the number of frames to 5 or 6) I tacked heavy cloth on the bottom of the cap or upper story, then laid three sticks on top of the frames in the hives, and put the cap or upper story on, filling it with oats chaff, and being careful to tuck it down tight around the edges. The bees do not show any signs of dysentery as I can see. They have not had a flight since I packed them for winter.

F. H. SEARES. Girard, Pa., Feb. 4, 1881.

[Your bees are uneasy from long con-

[Your bees are uneasy from long confinement, and were lured out by the bright sunshine. In similar cases it is a good plan to shade the fronts of the hives with slanting boards.-ED.]

'Cut and Paste."-That's the style; "Cut and Paste,"—That's the style; get down to it as soon as your usual energy can clear the way. From 40 stands at the setting out time in April, down to 24 by the middle of May, then up again to 54, with about 1000 lbs. of surplus, in 1 lb. sections, is the story of the of the writer's apicultural experiences for 1880. Bees in the cellar apparently are doing well, save a few uneasy and affected with dysentery. The temperature is from 30 to 40 indoors, during the past 3 months; while outside it has ranged from freezing to 38 below zero. There are fewer bees on the cellar floor than common during warmer win ters. Not a day has been warm enough for bees to fly since the middle of last November. Success to the Weekly. November. Success to the We Remember the closing cadence, GEO. L. SCOTT. and naste. Wadena, Iowa, Feb. 15, 1881.

Packed in Chaft. — Hurrah for chaff Packed in Chaft. — Hurrah for chaft packing! It saved our bees and we feel safe now to whistle pretty loud. We had a general thaw, some warm, calm weather, afording the bees a good fight, and us a chance to examine them. We found them all in good condition, a few wanting additional food, which we supplied, and several had a little dysentery. There was not a mouldy comb supplied, and several had a little dysentery. There was not a mouldy comb among the lot. Brood in all stages of development was found in a number of hives; in fact, in all the centre combs there were some. Do bees need water and pollen to rear brood? We doubt it. Being confined over 3 months where could they have got the water? In the fall, after all vegetation was dead, we took up 7 colonies, (given us by a neighbor who would have brimstoned them),

we made 2 of the 7, gave them empty frames and fed a little honey, and the rest, enough of sugar to see them thro the winter. These 7 made 2 strong col-onies, and they have considerable brood onies, and they have considerable brood started, but have had neither water nor pollen except what was contained in the food furnished them, which leads us to believe that they do not require either water or pollen until the warm weather of summer. Those who left their bees unprotected in this vicinity are losing many. One person near us lost 11 out of 13, another 7 out of 20, and all around we hear of losses.

W. H. STOUT.

Pine Grove, Pa., Feb. 13, 1881.

94 Days.—It is 94 days since my bees have had a fly, and to-day is the worst of any, for it is snowing with a gale of wind from the N. E. My hives are out of sight under the snow. My bees are well protected with boxes packed with chaff and straw, but the fall honey was so poor that, unless they have a fly soon, they will suffer badly. I will venture to say that one-half the bees wintered on summer stands in this section (northern Ill.) will go to bee heaven before on summer stands in this section (northern III.) will go to bee heaven before next May. I see, on page 28 of the weekly JOURNAL, you advise to plant basswood seed in drills. Please inform me when to gather the seed, and when to plant, whether in spring or fall. I have tried it various ways, but never succeeded in a single instance in making them grow, and am very anxious to set 300 or 400 of the trees around my lots. for shade as well as honey. I think 300 or 400 of the trees around my lots, for shade as well as honey. I think your article on adulteration the best I ever read, and I have read it to a great many people of our town, and they all pronounce it good. I don't think there is much danger of over-stocking in this cert of the country. part of the country, unless we can devise some better mode of wintering, for vise some better mode of wintering, for one winter they do well in the cellar, and next on summer stands, and vice versa. If my bees all die I shall get another colony if I have to selt the cow to get it, and the JOURNAL.

D. L. WHITNEY.
Rockton, Ill., Feb. 12, 1881.

[Gather the basswood seed as soon as ripened, either after or just before falling from the trees. In spring soak well in tepid water, then plant in drills 3 or 4 inches apart. When 1 year old, transplant into a sandy loam soil, if possible. Keep partially shaded till well developed, as the young plants will not stand much exposure to sun or drouth.-Ep.]

Bees in Northern Michigan. - The many reports of a poor season last year. in different parts, may show that this northern country is not such a poor place to keep bees as many may suppose. We are having pretty cold weather pose. We are having pretty cold weather now; the mercury going down to 20° below zero on the 2d inst., which, by the way, is the coldest we have had; at the present time it is 17° below, but no wind with it, or we should feel it pretty sharp. There is plenty of snow; about 3 feet in the roads on a level. Two years ago I started with the AMERICAN BEE JOURNAL (which no man who keeps bees ought to do without, especially the Weekly), and one colony of bees, and Weekly), and one colony of bees, and increased to three; the next year I increased them to II, using all the Dunham foundation they would work, and rearing my queens all in June, excepting one bought of Alfred II. Newman, which I suggestilly introduced. I think which I successfully introduced. I think which I successfully introduced. I think they have plenty of honey to winter on; they are packed in chaff on their summer stands with snow enough around them to help keep out the frost. We generally have snow enough for that purpose every year, so that the ground never freezes, the soil being sandy and clay loam the water works away as fast as it they and we are never troubled. as it thaws, and we are never troubled with mud or water in the hives. We with mud or water in the hives. We had honey from the willows and soft maples about the 1st of April last, then followed hard maple and an immense crop of fruit blossom honey, so much that I had to extract to make room for the queen in one hive, and although white clover blossomed profusely yet we received no honey from it. We had a fair corn of Alcilic, an objudying that I had to extract to make room for the queen in one hive, and although white clover blossomed profusely yet we received no honey from it. We had a fair crop of Alsike, an abundance from wild raspberry and blackberry; statements of success and failure. A

Acme, Mich., Feb. 4, 1881.

Deep Snow.—My bees are all on the summer stands, not having a dight this winter; they seem to be all right, but

keep the hives from being buried in it.

My straw hives 1 thinks "" My straw hives I think will take the prize again this winter.

11. Klosterman.
Shawano, Wis., Feb. 12, 1881.

Report Your Losses.—My bees did poorly last season. I have 60 colonies packed in chaff. 40 of these were very poorly last season. I have 60 colonies packed in chaff. 40 of these were very strong when I put them away for winter; but I very much fear that the long severe winter will destroy all that I have. severe winter will destroy all that I have. I will report when I take them to their summer stands, if it ever gets warm enough to take them there. I suggest that the name given to the Holy Land bees, be *Palestine* bees. I think it much more euphonious than "Holy bees." What say you, bee-keepers? I hope the readers of the Bee Journal will make brief reports for its columns. Let us know the worst "though the heavens fall." J. R. Baker. Keithsburg, Ill., Jan. 9, 1831. Keithsburg, Ill., Jan. 9, 1831.

Letter from Australia.—The American Bee Journal is full of most useful and interesting information. Its correspondents are evidently experienced and astute observers, and I have much pleasure in giving testimony to the excellence and variety of matter, all tending to make bee-keeping a popular and practical science, which appear in its columns.

S. McDonnell. its columns. S Sydney, Australia.

Cutting Bee-Gums.-1 have found a bee-tree—a large basswood. I wish to save the bees, when is the best time to cut it? Give general directions. Belleville, Ont.

[The best time will be in early spring. just after honey-flow sets in and before the combs are filled with brood. Fall the tree in the direction of the entrance, which is done by chopping the tree nearly off on that side first. When it begins to swing, a few strokes on the other side will lay it in the position you want it. Now chop (or saw) above and below the bees, and your "gum" is ready for transportation. If, however, the tree should break, in falling, right where the bees are located (which frequently happens), then save and transfer all the combs you can into frames, and get the queen and bees into a hive. which you should have provided in advance.—ED.]

Give us all the Facts.—Your issue of Jan. 26 reached us on Feb. 2. We gave an audible smile when we were informed, on page 28, that the weather is milder. Our weather has not let up enough to thaw for a month, and now our thermometer, the first days of February, ranges at about 18° below zero, with the thinnest kind of a north wind. While at work in our shop we have to feed our stove constantly and work lively to keep off the effects of Jack Frost. We have enjoyed eighty days of excellent sleighing. We think if the present weather continues, the chaff hive advoweather continues, the chaff hive advo-cates will have a winter severe enough to test their plan of wintering. We no-tice several reports of losses, and we hope hereafter each person will state how their bees were wintered, in chaff or in the cellar, or without protection. We winter in the cellar, and think it the very best plan. We have a few swarms packed in chaff, and we have wished them in the cellar several times during this extreme winter we are having, and

swarms and a bountful harvest, makes him feel very important, and his great success is spread far and near. But should he lose 25 per cent. of his bees in wintering, he is very quiet about men-tioning it. In fact, ten chances to one he does not mention it at all. The farmer that loses a few sheep or a few cows, thinks it no disgrace, and makes no con-cealment of the fact, but discusses the causes of his loss with his neighbors and tries to avoid disaster in the future. The bee-keeper has one advantage over the farmer; while the farmer has nothing to show after his loss, the bee-keeper has his empty hives, and they are placed carefully in their usual position upon caretiny in their usual position upon their summer stands, and no one would suspect loss unless an examination is commenced. Then if the bee-keeper is finally cornered, his loss is about so many. About means anywhere from 5 to 20, and he will not talk freely about it until the next fall. Knowing these peculiarities of bee-keepers (we are one peculiarities of free-keepers (we are one of them), we want full and straight reports. We will promise such a one on our part, and hope others will not be ashamed of their failures as well as their successes.

J. H. MALTIN.
Hartford, N. Y., Feb. 3, 1881.

Width of Sections.—Are not 1½ inches about the proper thickness for section boxes, where no separators are used? Are they not more liable to build the combs straighter than if they were thicker?

3. Can there not be more honey obtained without the separators than with them; and if so, what per cent.?

A. J. F.

East Liverpool, O., Feb. 14, 1881.

[1. No; we would use them 2 inches. 2. No: if you use starters.

3. There will, of course, be the addition of as much honey in each section as would be taken up in space for the separators. We do not think the separators make any perceptible difference in the amount of honey gathered.—ED.]

Bees in Georgia.—My bees went into winter quarters with but little honey, and some of them have perished on and some of them have perished on account of the weather being too cold to feed them. I am feeding some weak colonies now, hoping the weather will soon break, so that they can get a living for themselves. My bees stopped brood rearing very early in the fall and have not yet became again. Last year, brood rearing very early in the fall and have not yet begun again. Last year, brood rearing continued every month during the year. We are not troubled here about wintering; we leave our colonies out unprotected all winter. I think of stimulating soon, so as to encourage brood rearing. Peaches bloom by the 1st of March; then our bees can live without feeding. I am the only man in Ist of March; then our bees can live without feeding. I am the only man in this locality that has the movable frame hive, and I have the only station bees in the county. I have 30 colonies, 28 being Italians. I find comb foundation a great help, and shall send 50 lbs. of wax to be made into Dunham foundation. I am proud to see the Weekly Lower Lower in Level every word. JOURNAL come in. I read every word in it as soon as I get it. Success to it.

II. M. WILLIAMS, M. D. Bowden, Ga., Feb. 14, 1881.

Wintered in a Cave. —I have 35 colonies of bees, 10 in Root's chaff hives, and the balance in simplicity hives. shall get about as many more, and want to make a lot of hives, but am undecided which kind to make. I have my simplicities all packed in good boxes, and all appear to be wintering well, although we have had an unusually cold winter; thermometer has been as low as 28° below zero, and has remained below zero low zero, and has remained below zero for 10 days at a time. I like the simplicities for summer, as they are more convenient to handle, but which is best to make, chaff hives or the others, and pack in boxes. I have not been able to decide. In the winter of 1879-80, I had nine, all in simplicity hives, and made a cave on the top of the ground with ventilating tubes, &c. I put 51 in and took out 22 alive, and only 15 of these were able to give me any surplus. I obtained about 1000 lbs. from 15 colonies and their increase to 35 by natural

basswood yielded fair and buckwheat gave a big yield. I increased as much as I could, not expecting to get much honey to self; 200 lbs, of extracted honey being all I had. H. K. Beecham.

good season that ensures plenty of new swarming and dividing. I think I am in a good location here for bees, and him feel very important, and his great success is spread far and near. But should he lose 25 per cent, of his bees in for comb and 15 to 20 cts, for extracted honey should he lose 25 per cent, of his bees in for comb and 15 to 20 cts. honey. I have plenty of linn, white clover, sumae and Simpson honey plant growing wild here. I am well pleased growing wild here. I am well I with the Weekly BEE JOURNAL.

Greenwood, Polk Co., Iowa.

Placing Sections Crosswise, -Will bees work as readily in the sections where they are put on crosswise of the brood-frames?

PETER BILLING.

Pawnee, Neb., Feb. 10, 1880.

[We think it makes but little difference, so long as the usual space is left between the tops of the brood frames and the sections.—Ep.1

Feeding Candy.—My 25 colonies of bees had a flight on January 30, and Feb 10, but to-day is very cold. I am feeding andy made of granulated sugar and flour, laid on the frames under the quilt. I use the Langstroth hive. I have had a few for 15 years, but never knew the value of a movable frame until I took your Journal, and now I read every thing I can get on bee culture, and am much pleased with the Weekly. The last 5 years were poor honey seasons; our honey crop here is from white clover, there being no basswood, poplar nor golden rods near. I intend to sow some alsike and melilot clover this spring on waste places.

L. T. Mobberly.

Long Grove, Ky., Feb. 14, 1881.

Mitchell Hive.-I have 14 colonies in the Mitchell hive, in fair condition so far. I have used the Mitchell hive 2 years now and like it well. Bees done well here last summer. I commenced last spring with 6 colonies, increased to 14, and received from each colony 80 lbs. of extracted honey. I have received 5 numbers of the Weekly BEE ceived 5 numbers of the Weekly BEE JOURNAL. I am well pleased with it, and would not give it up for twice its cost. It is just what I want, as I am a new hand at bee-keeping, so I can hear form those who have kept bees for a good many years. Success to the Weekly BEE JOURNAL.

H. J. SMITH.

Ruchington, Wie, Eeb. 8, 1881

Burlington, Wis., Feb. 8, 1881.

Information Wanted.—I was much interested in Mr. James Heddon's article in the Journal for February 2d. He says: "I find that by the use of proper methods of adjusting sections on hives, and proper care after so doing, there is no need of those nuisances called separators." Now I should be very much pleased to have Mr. Heddon talk by the sections and sleep the sections are sections. tell how to adjust the sections, and also how to care for them after adjusted. rators, and from my experience, I find that metal is the only practical material to use, and the first cost of this is quite an item.

CARL TUTTLE.

Berlin Heights, O., Feb. 5, 1881.

Spider Plant.—Will stock eat figwort or spider plant? I have some waste ground on which I can use both for bee food, but it is unfenced. Please answethrough the Weekly Bee Journal.
E. S. Hopkins.
Jeffersonville, Ind., Feb. 17, 1881. Please answer

[We think they would not, unless there was great scarcity of other forage. Why not harrow in melilot? It possesses many advantages over either of the plants named, and the sooner put in the ground the better.—Ed.]

Bees Nearly All Dead .- My 40 colonies of bees are nearly all dead; if I have 5 colonies alive in the spring I shall be thankful. Some of them were in large boxes filled in with straw all around, and 6 inches of straw over them. I had 8 put up in that way, and not more than 3 of the colonies are now alive; the rest were in Langstroth hives, with straw in were in Langstrom lives, with straw in the caps, on the summer stands. I ex-pect nearly all the bees in this section will die this winter. H. M. Noble. Swedesburg, Iowa, Feb. 10, 1881.

#### THOMAS C. NEWMAN,

EDITOR AND PROPRIETOR,

CHICAGO, ILL., FEB. 23, 1881.

We can supply but a few more of the back numbers to new subscribers. If any want them, they must be sent for soon

. . . . . .

We have received quite a number of catalogues of supply dealers. We will notice them all in the BEE JOURNAL for next week.

In order to accommodate our foreign subscribers, and those in out-of-theway places, where mails are infrequent, we have concluded to put the numbers of each month into *Monthly parts*, with a printed wrapper. Those who desire it in that form, can hereafter have the BEE JOURNAL in monthly parts at the same price as the Weekly.

It would save us much trouble, if all would be particular to give their P.O. address and name, when writing to this office. We have several letters (some inclosing money) that have no name. Many others having no Postoffice, County or State. Also, if you live near one postoffice and get your mail at another, be sure to give the address we have on our list.

The following from a correspondent from Melbourne, Australia, is another illustration of the wonderful instincts of the honey bee:

"A singular circumstance is reported from a hot, dry valley in New South Wales. Last year the drought there was of long duration, and the denizens of the apiaries suffered much from it. This year the bees have made provision against a similar emergency. They have filled a large number of the external cells in every hive with pure water instead of honey. It is thought that the instinct of the creatures leads them to anticipate a hot summer."

Mr. Robinson, on page 58 of the JOURNAL, gives some items of history concerning the first importation of Italian bees into this country. We are sorry to see his reflection concerning "jobbery," and the dying of the bees belonging to the Government, en route. We had an interview with Mr. Parsons while in New York, and should be very sorry to intimate that he did any thing wrong in the matter. We are not able to contradict M. Robinson's statement, but we certainly do not endorse it. We did not notice the sentence until the "forms" were made up, and nearly ready for the press.

© On account of unfavorable weather the convention at Monroe Centre, Ill., met on Feb. 8, and there being but few present, adjourned to the same place on March 29, 1881.

A. RICE, Pres.

BEE JOURNAL will be sent free to any names that may be sent in. Any one intending to get up a club can have sample copies sent to the persons they desire to interview, by sending the names to this office.

#### "Come: Let us Reason together."

A despondent bee-keeper writes: "I am about ready to abandon the pursuit of bee culture for something that will pay better." But what is there that is always prosperous.independent of times and seasons?

Fruit fails once in a while,—does the fruit culturist cut down his trees and burn them, and then search for something that pays better than raising peaches, apples or plums? Crops of grain often fail in large districts, as the result of atmospheric influence, insect depredations or unpropitious weather. Will farmers then cease to plow and sow, and go in search of something that will pay better?

The present severe winter has been very destructive on all kinds of live stock. Thousands of cattle have already died on the prairies and western lands,—will the breeder give up, and seek some other business that will not be so destructive and that will pay better?

Storms on Lake and ocean cause the the waters to yawn and swallow many a valuable vessel and cargo—does the mariner become disgusted and look for some business that has no drawbacks?

The manufacturer, the banker and the merchant often have to grapple with financial distress and commercial panics, do they forsake the counter, desk and factory, and look for some business that is without loss and trouble.

Prof. Riley predicts another visitation of the 13 and 17 year locusts, both broods coming together this year, which in their destructive career will eat up vegetation, and leave the earth bare in many and vast districts—will the agriculturists therefore, leave the fruitful fields of America and go to the barren hills of Italy: or the burning sands of Arabia?

No, indeed! such reverses but stimulate progressive men to further diligence and more dauntless courage. When the farmers, herders, fruit growers, merchants and bankers set the example, it will be time enough for beekeepers to become discouraged. *Until then*, hold on perseveringly; for the average years will make as good a showing for bees and honey as any other busi-

😭 " Can I put in my advertisement once each month and reach all the readers of the Bee Journal?" This is a question that is asked by several. Of course you can. The first issue in every month goes to every subscriber-monthly semi-monthly and weekly. But as 19 out of every 20 of all our subscribers take the weekly, it is a matter of small moment which week an advertisement is inserted. Those who are too poor to take a weekly, or those who are not enough interested in the art to get and read it, will not benefit an advertiser very much. Advertisements may be inserted every other week, or once a month, or weekly, as desired.

Any one desiring to get a copy of the Constitution and By-Laws of the National Society, can do so by sending a stamp to this office to pay postage. If they desire to become members, a fee of \$1.00 should accompany it, and the name will be duly recorded. This notice is given at the request of the Execntive Committee.

#### Now is the Accepted Time.

The season is rapidly approaching for the formation of plans for the summer's operations; and by the time this number has reached its respective readers. many can "take stock" of what is left and make almost exact calculations regarding the work to be done. Of course. the first question to be settled will be whether to manipulate the apiary to obtain the largest possible increase in numbers of colonies, or with a view to the production of honey alone. There are many who will "trust to luck" to shape their course for the future (as undoubtedly they have largely done in the past), and these will, we are sorry to say, be found to constitute the majority. But the calculating, careful, prudent, intelligent, successful bee-keeper, will form his plans in advance, and work systematically with a view to their accomplishment.

If increase be the object in view, the first warm, pleasant days will be turned to advantage in looking over the hives, cleaning up the combs (preserving the bright, straight ones, and melting the others into wax), selecting the strongest and best colonies in which to rear queens and drones, and overhauling the hives and frames so that the work of dividing and building up can be rapidiy and systematically pursued. Make preparations, also, for prompt and liberal feeding at such times as the bees cannot gather honey. If there is a scarcity of desirable combs, now is the time to order your foundation; have it shipped by freight, and accept none but the brightest and best. If your hives are not perfectly satisfactory, or you are likely to need more, order them now, in the flat, and to be shipped by freight. Now is the time to ascertain if anything else may be wanted, and to procure it.

There are many, however, who will wish to devote their time and resources to the production of honey—having now about as many bees as they wish to care for, and depending upon natural inerease for the number they may yet desire. These have much work to perform in building up their colonies to the requisite strength to gather honey rapidly and profitably. Now is the time to manufacture or order extra hives, surplus boxes, sections, extracting frames, comb foundation for brood chambers or for section boxes. If you have occasion to buy anything, send your order only to reasonable, responsible dealers—such as have built up a reputation by honorable, upright dealing, and who are not ashamed to liberally advertise their merchandise. Send them your order early, to enable them to fill it satisfactorily, and to give you the benefit of the cheapest transportation. There will be many wet, disagreeable days, untit for out-door work, when the time can be profitably employed in putting together the hives, frames, sections, etc.; therefore, order everything flat. Do not delay ordering an article till you want to use it—it is short-sighted and disastrous economy. Be particular to state just what you want and only what you want.

Now is the time to make choice of waste or poor-producing soil for planting. Select and order your seeds at once—order liberally. Take advantage of the first general thaw to get in your clovers. Better have less bees and better pasturage, than more bees and poor pasturage.

We cannot close this article without expressing the opinion that, although the winter has been most disastrous to bees on this continent, it has been very favorable for the production of honey the coming summer, and those fortunate enough to have retained their bees will realize satisfactory results.

#### What will the Weather be?

In the East, during the second week in this month, the weather was mild and the "January thaw" took place. This allowed bees a good flight, and thousands of colonies were saved, which otherwise would have perished.

In the West, it is now a matter of much importance to know what the weather is to be for the next three or four weeks. Many colonies of bees need a "flight" so badly that if it cannot be obtained, death will be the result. They also need "feeding," which we are happy to say Prof. Vennor says may be possible this week. The Professor says:

"With the beginning of the last week of the month, brilliant, mild, spring like weather will again appear, melting the snow and rendering the sleighing impossible in some localities.

possible in some localities.

A few days before the close of the month high winds are likely to prevail, with gales around New York, Long Island Sound and other points, with blustry weather in Canada and the Northern United States. The last two days are, however, likely to be fair, and the month

however, likely to be fair, and the month will end with little snow on the ground. March will come in like a lion. The beginning of the month will be characterized by storms of wind, which will culminate during the second week in heavy gales throughout the United States. On the 2d there will be heavy snow storms in Quebec and Montreal. On the 8th snow storms are probable in 8t. Lonis, Kansas, Arkansas and Indian Territory. On the 9th and 10th gales are probable around New York, Boston and intervening points, and snow storms pretty general.

About the 7th and 8th, storms of wind

About the 7th and 8th, storms of wind and snow may be expected, followed by rain and slush. This condition of things will terminate in a cold dip about the 13th or 14th, with a fall of snow. On the 13th, cold weather may be expected in Toronto, Sarnia and other points

St. Patrick's Day will arrive during the cold snap in Ontario and Quebec and the Northern States, while rain, snow and sleet will prevail southward as far as Washington, and snow and rain will fall in the Canadian maratime provinces. With the beginning of the third week of this month general snow falls, from the Lower Provinces westward to Chicago, are likely to prevail. They will be succeeded by utild and spring-like weather, with indications of rain and snow; while heavy rain storms will probably set in in the Lower Provinces and portions of the United States.

During the last week, heavy rains will prevail throughout Canada, with a probable for the provinces of St.

During the list week, heavy rains will prevail throughout Canada, with a probable fall of snow in the direction of St. Louis, Mo., and easterly gales in the in the Gulf of St. Lawrence. There will be signs of the opening of navigation in Ontario, while snow falls will be probable at points west of Montreal; On the 17th heavy rains will be likely in the Lower Provinces and Quebec, and through portions of the United States; and from the 20th to the end of the month there will be wet weather in Halifax. On the 30th the weather will be blustry, with sleet and snow possible at many points east and west. The old adage about March when it comes in like a lion will not be falsified, as the month probably will end lamb-like.

"Our Letter Drawer" this week, for many are watching with interest the reports from all over the country concerning the bees, how they are doing, what the prospects are, etc.

#### MISCELLANEOUS.

Feeding Bees. - Mr. L. C. Root, in the American Agriculturist, gives the following as his views on the above subject:

The frequent inquiries at this season, as to the best feeder to be used, proves that many have not furnished their bees with sufficient stores to carry them thro the winter. Lam positive that our good winter. Tain positive that our good yield the past season was very largely due to the fact that our bees were in line condition in the spring. Still if I had bees without sufficient honey at this seasons of the many I dead back or offson of the year, I should make an effort

on of the year, I should make an electronary to save them.

The first thing necessary is good food.

Do not take the advice of some and use cheap food, made from grape sugar, which they recommend. We know of nothing better than best "A" sugar.

Next in importance is the manner of preparing and feeding it, as this should differ according to the season. In winter, the food should be as free from moisture as is possible, and be placed where the book are how you've peops to where the bees can have ready access to where the bees can have ready access to it. Prepare a piece of board of suitable thickness, just large enough to cover the top of the frames, and not allow the warmth to escape. Nail cleats on one the top of the frames, and not allow the warmth to escape. Nail cleats on one side, at each end, to prevent warping, and with a sharp chisel scoop out the centre of the board, forming a trough large enough to hold as much as it is desired to feed. Then make a quantity of candy as follows: Put the sngar in a sauce-pan with a little water and a small preparation of flour and holl, stirring it proportion of flour and boil, stirring it until it begins to grain. Pour this candy into the trough described, and when dy into the trough described, and when sufficiently cooled remove the cover of the hive and invert the board upon it, so that the food comes over the cluster of bees. This being the warmest place in the hive, the bees can secure the food

most readily.

As to the best method of feeding liquid food, there is a variety of opinion. I would not advise the feeding in liquid f would not advise the feeding in Apple form at this season, but as in spring a feeder for this purpose will be needed, I give my preference. I think that the Van Dusen feeder, shown in the engrav-

ing, answers all the requirements better than any other. This is filled, as shown at the left hand, and when inverted and placed over the opening at the top of

placed over the opening at the top of the hive, no honey or syrup will escape, except as it is taken by the bees. As 1 am an earnest advocate of in-door wintering, I urge the readers of these notes to carefully observe the re-sults of the severe weather of the pres-ent winter upon the bees being win-tered out of doors. I admit that they may be safely wintered out of doors during milder winters, but I think the experiences of the present season will convince many bee-keepers of the necessity of adopting some system of wintering their bees adequate to the emergencies of our uncertain northern climate.

How to Ripen Comb Honey .- In the Agriculturist, Rochester, N. Y., Mr. G. W. Stanley remarks as follows on the above subject :

enough sweet from the candied honey to sour and press off some parts of the capping, and thus form a leak. Now on the other hand, if the honey is taken from the hive and put in a warm or tight room, (as the honey will keep the temperature up to 90 or 100 if the room is well filled with honey), the process of curing goes on the same as in the hive; well as the honey becomes righted. and as the honey becomes ripened, the nercury will begin to fall and in about two weeks you will see no difference from the honey being in the room. In trom the noney being in the room. In 1879, my honey room, 12 ft, square and 8 ft, high, was kept at 90 (having 4,000 pounds of honey in said room), when the mercury stood at 60 to 80 outside, and none of my honey troubled me by becoming granulated or souring. Honey away in this way will show no signs of cured in this way will show no signs of eandy before March or April, and not then unless subjected to a great amount of very cold weather.

Extracted honey is more liable to granulate than comb honey, as it is tak-

grammate than comb honey, as it is taken from the bees usually as soon as it is stored, and before they have had time to evaporate the water that is in it, and so there is more water and less honey. This can be cured by putting it on the stove and bringing it nearly to a boil, ekinming off the imporities and the stove and oringing it nearly to a boll, skimming off the impurities, and the honey will keep until very cold weather before it will show any sign of granulation. When extracted honey becomes

before it will show any sign or grand, tion. When extracted honey becomes hard with no water to be found, it is ample proof of its purity.

I have given the most common way for extracting, but will now give the correct way. Leave the honey in the hive until it is all capped over, and then it will be cured as well as box honey; then with a sharp knite for the purpose, remove the capping and throw out with the extractor, putting the honey in a warm place, covered with a fine cloth or screen, to keep out flies a fine cloth or screen, to keep out flies and to admit the air, and your honey will become thick, and keep for a long

#### North-Eastern Convention.

We regret to say that the third day's proceedings have not yet come to hand, although sent us by Secretary House some ten days ago. The "snow blockade" is the cause we suppose.

President Root's annual address on the subject of "Queen Bees." is as follows:

It is not my purpose at this time to discuss the merits of the different races of bees, or their crosses, neither to give the processes of rearing queens, which have many times been set forth; but rather to call attention to the all-important consideration of good queens. When we remember that the one queen of each hive must deposit all the eggs, and that when the weather is suitable. she will, if an opportunity is afforded, deposit all that her qualifications will allow, and when we also remember that the amount of honey which will be stored depends so largely upon the num-ber of bees which are present to gather it, we catch a glimpse of the extreme importance of securing superior queens. Let it be understood that I am looking at this question from the standpoint of one who desires such bees as will secure the largest quantity of honey. This means, tirst, such colonies as will breed latest in the fall to secure the largest number of young bees to go into winter quarters. Second, such as are vigorous quarters. Second, such as are vigorous and will defend themselves best and also winter best. Third, such as will go through the spring months, and suffer least from spring dwindling. Fourth,

is a great wonder that we find our stock occupying so high a position as it does at the present day. Well may we feel gratified that the great progress that has been made within the past few years, has arrested this hindrance to bee culture, and turned the attention of beek preserve to this all-important demand. keepers to this all-important demand. Let us notice first the condition under which queens were reared during the past. In many instances we must admit that during poor seasons only the best stocks would swarm, which secured the young queens from the best colonies only. Another fact in connection with this method, which resulted in advan-tage, was that in the uncared-for condition of our bees in those days, only the most vigorous survived the winter, thus destroying the poor stock, and perpet-uating only the best, which had succeeded in gathering sufficient stores. These conditions which arose from natural causes and not from the incelligent care of the bee-keeper have tended to elevate rather than to hinder.

elevate rather than to hinder.

But let us notice some of the hindranees. All who are familiar with the habits of bees are aware of the large number of queens which are, or would be superseded during the season, when left to their natural tendencies. The queens of such colonies are information. telt to their natural tendencies. The queens of such colonies are inferior in various ways, some of them so poor that they have just enough fertility to deposit an egg from which a queen may be reared. Compare the quality of a queen moduced under such circumstanqueen produced under such circumstaues with one reared with the attention that I shall indicate as essential.

The truest of sayings that "blood will is as true of bees as of any form

of animal life.

Where is the bee-keeper of much experience who does not in many instances feel the force of this difference each season? In an apiary as ordinarily con-ducted, colonies will vary in production of honey all the way from nearly nothing up to a very satisfactory amount, and this variation comes more largely from the difference in the quality of queens than from any other one cause. will ask, how can all these obstacles be removed and the best queens be obtained? I answer, in the same way as all improvement is accomplished, by an intelligent persistent application of the best views of all interested. Much has been done already, but more remains yet to be done. Many of us have been, and are still working in various ways to improve our stock. We, with many others, have secured stock of the very best quality we could find, and from many different sources.

Here, in brief, is the course that must be pursued. Stock must be obtained of the very best possible quality and of different strains. Queens must be reared for their actually desirable qualities, and not for color or show. They must and not for color or show. They must be raised at the proper season when the most favorable conditions may be se-cured. The queens must be derived from one strain, and the drones with which they mate from another, thus producing a direct cross. In this way the two colonies which munifest the most two colonies which manifest the most superior qualities may be used, from which hundreds of queens may each season be reared and fertilized for introduction into hives in other apiaries.

Until the practice of fertilizing in confinement comes into more general use, our location for rearing queens must be such that drones of inferior quality will not interfere with the carrying out of our plans. We must use rying out of our plans. We must use great care in every particular, even if the expense is increased. It will be money well spent. I am no advocate of cheap queens, if reared at a sacrifice of less methods. best methods.

The question is frequently asked, to what age can we profitably retain our queens? This will depend upon the system of management. If the ordinary methods of the past is practised, and a queen is required to deposit but few eggs each season, she may continue

and put in a cool or damp place the honey will granulate, and the little water that is left in the honey will rise to the top of the cell, and will gather just enough sweet from the candied honey at the present day. Well may we feel the present day. Well may we feel the present day are that the continual process that here is a great wonder that we find our stock of actual practice have proven the corrections of the position that assumed. this also continued by the experience of those who have noticed that colonies containing young queens are most vigorous, other conditions being equal. I am often asked if imported bees are preferable to home-bred. I think not, but I am for from disgouraging the inpreferable to home-bred. I think not, but I am far from discouraging the importation of queens. We need the new blood, but let it he selected with greatest care. All of us who are in any way interested in the improvement of bees in America, are largely indebted to the many enterwising men, who at much many enterprising men, who at much risk and expense have so successfully introduced new and desirable strains. Their labors should be generally appre-

eiated.

The skill and thought which have been given to this subject in this country for several years past, have resulted in an improvement upon imported stock. Who would think of breeding from an imported queen to any extent without first testing her?

And by this 1 do not mean a test of

And by this 1 do not mean a test of color of her queens or workers. I have known equally desirable stock both in dark and light colored bees. We have stock at present of dark workers that are second to none as honey-gatherers, and are of extra disposition. I speak of this to discourage too strong effort in the direction of color without due consideration of other qualities. sideration of other qualities.

Let us round up our standard of excellence until all valuable qualities shall be attained, not ignoring beauty, but let those appear handsomest which prove themselves best.

Read before the North Eastern Convention

#### The Wintering of Bees.

GEO. W. HOUSE.

The great and all important question now to be understood is, how to manage the apiary so as to carry the bees successfully through the interval from the 1st of December to the time of fruit blossoms in the spring. Give this knowledge to the apiarian and bee-keeping is a success. With all our noted apiarists, such as Quinby, Langstroth, Wagner and others as leaders in apiculture, we yet find many difficulties to encounter, that their wisdom has not sufficed to lead us to that desired goal—"perfect success." Hence it is that this subject of wintering bees is of leading importance and well deserves the earnest thought, study and careful experiments of our most practical apiarists. Then of our most practical apiarists. Then in discussing this all important theme, let us consider the facts that bear upon it glean what we can from experience and then see if we can arrive at justified conclusions.
With the benefit of our experience of

over thirty years, I shall endeavor to give facts with the practical workings as derived from what knowledge we at present possess. We will commence by present possess. We will commence by asking: "What are the requisites for

asking: "What are the requisites for safe wintering?"
It is a fact that bees, from their confined situation in winter, cannot excrete excessively without rendering the atmosphere about them unwholesome; this, with undue fecal deposits, is sure to bring disease. It is further true that excessive excretion of the feces is causally long continued confinement. ed by long continued confinement. Therefore our first axiom: Bees to winter successfully must have one or more

purifying flights.

The novice need not be told that bees take food during the winter. It makes no difference what the temperature, more or less food is consumed. Therefore our second axiom: To winter bees they must have sufficient stores of wholesome food.

It is further true that bees are com-

It is further true that bees are com-It is further true that bees are compelled to move from one comb to others to secure their usual amount of food. This duty they cannot perform with a low temperature; hence our third axiom: Bees to winter well must be protected from the extremes in temperature. Furthermore it is a fact that with a high temperature bees move about the bive to carry their stores nearer to the Comb honey is capped over by the bees just as soon as it is sufficiently those whose queens are very profific during evaporated so that it will not sour in the entire season.

When we consider the many generations taken from the honey is stored. If the honey is taken from the hive as soon as capped over by the ter least from spring dwindling. Fourth, those whose queens are very profific during the entire season.

When we consider the many generation is the profit of four or even five years; but if she is forced to her utmost capacity in egg-laying, she may exhaust her fertility in two, or at most, three years.

At one of our meetings during the littly in two, or at most, three years.

At one of our meetings during the littly in two, or at most, three years, and with a sudden fall of the live tained and perpetuated the races of bees, have succeeded each other without is statement of my belief in the truth of mercury, many bees are frozen to death

before they can again reach the cluster. Therefore axiom four: To winter bees ely, they must have easy access to the different parts of the bive.

It is an admitted fact that a worker te with three months of busy life, is aged and infirm; that a worker bee hatched in October will be in better condition at the age of six months than the one just mentioned at the age of three months; furthermore, old bees cannot generate as much heat as young ones. and as winter is the trying ordeal and with them the great struggle for life; no apiarist should expect that a colony of old bees will be able to stand this struggle, and in the spring build up the staggering colony to the desired strength, any more than they would expect an aged person to perform the manual labor of a robust healthy young man. Hence axiom five: To winter bees well they must be strong in numbers, as well as young and full of vital-

ity.

Experience shows the importance of proper absorbents over and above the heesin winter. Whatexperienced apiar-ist has not noticed the moisture in his ist has not noticed the moisture in his hives during the winter, which often produces mouldy combs, and during cold spells changes into frost, and often approximates too near the cluster, keepthem from the needed stores; while in higher temperature it produces dampin higher temperature it produces dampness, causing the bees to gorge themselves with honey to keep up the desired animal heat, and this in turn will result in a loss to the bees through the so-called disease, dysentery. Therefore to prevent any ill effects from an accumulation of these elements of destruction, we must cover them with some absorbing material that will not permit a draft of cold air through the hive, and at the same time a non-conductor of heat. same time a non-conductor of heat.

Thus far we have shown that the requisites to safe wintering are embraced in the following self-evident truths, viz: -A sufficient quantity of well rip-

2d—One or more purifying flights du-

ring the winter.

3d—A proper protection from the extremes in temperature.
4th—An easy access to all parts of the

5th-Sufficiently strong in numbers

and young bees.

6th—Proper absorbents over the hive and above the bees.

Now let us see how we can best sup-

ply the necessary requirements.

Our first requisite is a sufficient quan-

ity of well-ripened honey.

If we do not extract the honey from the brood chamber, we will have but very little to look after, unless it be at the end of a poor season or with late swarms. end of a poor season or with late swarms. Here the apiarist must use his own judgment, as circumstances after cases. Some late colonies will want to be united, while others with a good family of bees and a sufficient quantity of comb will pay best to feed enough to carry them through until spring, or exchange combs with those that have to spare.

I am not in favor of extracting the I am not in favor of extracting the unsealed honey from the brood-chamber in the fall. Our experience is such as to convince me that this is all useless. Bees will not seal the honey unless it is Bees will not seal the honey unless it is sufficiently ripened, and when we reach the middle of November, their stores will be all sealed honey, as every observing bee-keeper knows that the bees move the honey from the outside combs to the middle of the hive.

Of course our surplus arrangement should be in place during a flow of fall honey, that the bees do not crowd the queen in her labors. Then again there are some who charge the heavy losses

are some who charge the heavy losses to the bees sucking the juice from grapes and the refuse from a cider mill. I am thoroughly convinced from experience

that this is not so.

One of our apiaries is located close by produce more than are grown in the im-mediate vicinity of our home apiary,

is one of the requirements of nature. Bees that are prepared for winter on their summer stands will enjoy such their summer stands will enjoy such flights whenever a favorable opportu-nity offers, providing the attentive apiarist is careful to keep the entrances always open. But those wintered in-door, if not permitted a flight from No-vember to April will become uneasy, and in almost every instance they will be attacked with dysentery, causing their light and beavy losses.

dwindling and heavy losses.
Undoubtedly we have one of the best Undoubtedly we have one of the best winter repositories that could be constructed. It is very dry, and has the desired ventilation; the temperature never falling below 37 degrees when only partially occupied. We have wintered 180 colonies in this cellar without losing a single swarm. Then again, if confined four months without a flight, they would surely come out in had contracted. confined four months without a fight, they would surely come out in bad condition; but if they secured a good fight during January or February, or both, they were just as sure to come out in better shape. The oftener the flights the better they winter. Therefore I am convinced that bees wintered in repositories should be allowed a flight at every nones should be allowed a flight at every favorable opportunity. It gives them a chance to discharge the feces and clean up the hive. Here we have another objection to in-door wintering. As we many times have such opportunities of short duration, an apiarist with from 100 to 500 colonies, could not give his bees the desired flight, while if preserved. bees the desired flight, while if prepared on their summer stands they would enjoy the desired flight and return in a healthy condition.

The third requisite: A proper protecion from the extremes in temperature. Those wintering in repositories are enabled to guard against these changes without much trouble, but those wintering out-door must necessarily give sufficient protection.

Perhaps I can best illustrate by giving our method of out-door wintering. First build a temporary shed facing to the south, by driving stakes in the ground, nailing up the back ends with any odd boards. Lay on the roof-boards any odd boards. Lay on the roof-boards in such a manner as to carry off the water, that it may not leak down on the packing; the roof should slant towards the back. It can be built any desired length, and just high enough to admit of easy packing around the hives. Now lay some securiting or pales on the ground. of easy packing around the invest. Now lay some scantling or poles on the ground and on these place a bed of straw or chaff, treading it well down between and over the poles, so that the hives should set 8 or 10 inches from the ground. Place the hives on this bed of straw about 6 or 8 inches apart, leaving about 10 inches space at the back. Now pack chaff or fine straw firmly between the hives and at the back, packing as high as the tops of the hives. (The method of preparing the hives I will give a little footback.) further along). Contract the entran and your bees will improve the first Contract the entrances portinity for a flight, and they will have no desire to fly out under unfavorable circumstances. Prepared in this manerremnstances. Prepared in this manner we are guarded against the extreme in temperature, and with the benefit of over twenty years' experience in in-door wintering, and various other methods, I am satisfied that this method is preferable to all others, giving the most satis-factory results, besides being the cheap-, attended with the least labor, and est, attended with the least labor, and by far the most practical mode of win-tering in this latitude. I will winter bees in this way with as little trouble, and as successful as any living man.

4th—To winter bees safely, they must have easy access to the different parts

I contend that this is an all-important a contend that this is an all-important factor in successful wintering. After the fatal winter of 1878-79 I examined many hives in our neighborhood that had been wintered on their summer stands without protection. I found many hives where the bees had actually external to death with planty of honor. One of our apiaries is located close by many hives where the bees had actually alrage cider mill, but our percentage of starved to death with plenty of honey losses is no greater in this apiary than in the hives. During the long continued with the others, everything equally constead they were amable to pass over the sidered. In regard to grapes, I would tops of the frames to procure the needed say that there are but few localities that, supply, while if there had been passage produce more than are grown in the im- | ways through the centre of the combs many would not have perished.

Then again with a higher tempera-

suddenly, when many bees are caught away from the cluster, and perish before they can gain access to that part of the hive where the bees are clustered. To obviate this difficulty, bore a ½ inch hole in the side of the hives a little above the centre of the frames; then with an iron spear pierce through all the combs. This should be done during the month

of October.

Axiom 5: To winter bees well they must be sufficiently strong in numbers and young bees. This is a complex and young bees. This is a complex question, and one that I am not able to fully solve. As to being strong in number, I am satisfied is true. But in regard to young bees I am somewhat perplexed. At one apiary of upwards of 150 colomies, the bees have not stored a pound of the larger of the property of the perpendicular to t of fall honey in three years; they were fed nothing, and ceased brood-rearing in September, still they were wintered with a loss of only 3 per cent. At the other two apiaries fall honey was stored and brood-rearing kept up into October or November. The bees in all 3 apiaries or November. The bees in all 3 apiaries were prepared for winter in the same manner, but the losses in these apiaries manner, but the losses in these apiartes were larger than in the first named apiary. Then again in these two apiaries where fall honey was stored, I have noticed that some colonies that kept up brood-rearing late, wintered better than those whose brood ceased to hatch in arly September, and *vice versa*. I think ean assign causes in many cases. early September, and vice versa. However a plenty of young bees is desirable, it certainly cannot be detrimental.

Our 6th and last truth: Proper absorbents over the brood-chamber is universally acknowledged an essential point in successful wintering. There is nothing equal to a straw mat for this purpose. It has all the desired qualipurpose. purpose. It has an the desired quarties, is the most durable, and is cheap and easily made. Our hives are so constructed as to use surplus boxes at the sides of the brood-chamber. In winter this space (2 inches wide), is occupied by a chamber a partie also already yet. by a straw mat, a mat is also placed over the frames, thus making the sides of the brood-chambers of straw mats. The second story or chambers of the hives should be filled with chaff or fine straw. We credit our success in wintering largely to these straw mats. From late experience I am of the opinion that experience I am of the opinion that dysentery or dwindling is attributable to an excess of pollen instead of unsealed honey. The cells being partly filled with pollen, are finished up with honey and capped over. The bees consume the honey, leaving the pollen exposed to the damp atmosphere, and when in excess of their wants becomes sour or excess of their wants, becomes sour or so changed as to produce the disease. This element should be given the earnest study and experiments by our leading apiarists. I think it will solve a mys-

#### SPRING MANAGEMENT.

The whole year depends more or less upon spring management. A very large per centage of the losses occur between April 1 and May 1. There are tween April 1 and May 1. There are many causes to assign for these losses many causes to assign for these losses, but we have not the time or space to give them here. The most disastrons cause is from dwindling, and there are various causes that produce this wasting away, among which are dysentery, a lack of bees to keep up the desired and the changes in temperawarmth and the changes in tempera-ture. We have already spoken of dysen-tery, therefore I will refer to only one tery, therefore I will refer to only one cause not spoken of before. It is a positive fact that the heavy losses in this country have occurred during those winters attended with a heavy fall of snow. There being no frost in the ground, there is a peculiar dampness (varying in different soils), that arises from the earth that is a sure cause of this dreaded disease. I am fully satisfied from past experience that there is but one way to prevent this dampness. hed from past experience that there is but one way to prevent this dampness, &c. Have your hives set on a bed of chaff or straw, and keep the snow cleaned away from the hives, so as to leave the ground bare. The earth will thus be-come frozen and thus cut off this dampness, and allow the bees fresh pure air. Those colonies that have not a sufficient family to keep up the desired heat for brood-rearing, should be given a frame or two of hatching-brood drawn from way injurious.

Our second axiom: Bees to winter successfully must have one or more parifying flights during the winter. This

up, and here, as all through spring management, the apiarist must necessarily use his own judgment, but always aiming to get his colonies strong as early as possible. The plan of taking from the strongest and giving to the weaker is the most practical yet known. A little judicious stimulating at times is also dvisable.

Bees prepared for winter on their summer stands, should not be unpacked before warm weather, so as to avoid the change in temperature. Bees wintered in cellars suffer the most from these

in cellars suffer the most from these changes, and I am convinced it would pay to give such a proper protection after setting on their summer stands.

Before closing I will say: During cold spells do not disturb your bees, not even as much as to allow walking on the hard frozen ground near the hives. When it is warm, that is, when it is thawing in the shade, or nearly so, open the enthe shade, or nearly so, open the entrance to the hives, and with a wire bent at right angles about two inches from the end, clean out all dead bees, &c., that are on the board. This can be done that are on the board. This can be done without disturbing the bees. You should also raise the second story or chamber a very little, to admit of a slight circulation of air; this will cause the chaff or straw packing to become thoroughly dry. As soon as the damp-ness in the hive and chamber has thus been dispelled, let the chamber back to

peen dispened, let the chamber back to place, contract your entrances, and your hives are again in a healthy condition. Before moving bees in the cellar or repository, the hives should be thor-nighly dry and in moving district. oughly dry, and in moving, disturb the bees as little as possible. When they are removed from the cellar, it is impor-tant that each hive shall occupy the same position as in the fall before mov-

ing.

In writing this essay, I have given instructions for this latitude, but the main principles will hold good in any

Fayetteville, N. Y., Jan., 1881.

#### The Marketing of Honey.

L. M. WAINWRIGHT.

"It has been estimated that there are 300,000 persons who keep bees in North America—an average of 10 colonies each will place the number of colonies at three millions, and if these produce so little as twenty-five pounds each, the honey product amounts to pounds valued at \$12,000,000. to 75,000,000

ounds valued at \$12,000,000.

"If the wax product of each colony is only one pound at twenty cents per pound it will amount to \$600,000.

"Now the best methods for placing this enormous product upon the market is a subject of vast importance to honey producers.
"Any method that will add one cent

per pound to the marketable value is worth to them three-quarters of a million of dollars; and any error of management, eausing a reduction of one ent per pound, is to them a corresponding loss.

ing loss.

Hence the principle object in marketing honey is to create a demand for it. And to create a demand it is necessary to produce it in such a style as will attract and tempt the consumer, and so pure that you may gain the reputation of being honest. For it is well known to each of us that adulterations have been the greatest hindrance we have had in striving to make honey a staple article and that suspicion or distrust having found its way into the public mind is a very obstinate and disagreeable enemy. able enemy.

As to the kind of honey we shall pro-

As to the kind of honey we shan produce, whether comb or extracted, we should ascertain what our respective markets demand; and then dilligently apply ourselves to the work of meeting

that demand.

Should it be comb honey that your patrons or your vicinity favors, bend every energy toward the raising of pure comb honey in the most marketables shape, and leave no stone unturned. Ambition is an absolute requisite to success in any branch of industry, trade or learning, and nothing is to be hoped for without it.

bloom that produced it and the probloom that produced it and the producer's name and address. These should be placed in a neat crate, probably ten or twelve in each crate. In order to expose the contents to the eye, and thus cause our carcless "freight-lifters" to "Handle with Care," the crates should be so constructed that they may be glassed, then with a larger label on the lid of the crate, we have an attractive package which can be shipped almost any distance, or will look neat on a grocer's counter.

Should it be the pure nectar without another, indigestible secretion, that the traost ready sale, put it up in one-pound glass jars, cork them, cap them nicely with tin-foil and label them with the name of the kind of bloom that produced it and the producer's name and address. Or for shipping long distances it should be put up in five or ten pound cans or fifty pound spruce kegs.

In every case label with the producer's

kegs.

In every case label with the producer's name, for then the names of those persons whose reputation becomes established by honesty will serve as a guarantee of purity, the others will be shunned. It is well to put a small label on the jars stating that pure honey will granulate on the approach of cold weather, and that placing the jars in water and heating it gradually will reduce it to a liquid without injury to its quality or favor.

duce it to a liquid without injury to its quality or favor.

Have everything neat and clean, no broken combs, no leaking jars and no soiled labels. Try to have the whole look like it had been put up by some very particular New England house-keeper, and I warrant it will look nice and attractive.

Now for marketing this tempting and delicious sweet. With comb honey in your own town or city, take a sample, a fair sample of what you have for sale, and go from house to house, do not miss one, and show to each lady of the house your honey and if necessary let her taste it, take her order for one or more pounds if possible, and at a reasonable price, and I warrant you will in a short time have a sufficient demand for your honey to pay you many-fold for you trouble in introducing it.

In placing the extracted honey before

the people one is met with more opposition than with that in the combs, for persons in general are not aware, that the latter can be adulterated as well as extracted honey and at a much greater profit to the adulterator, and it is necessary to explain to them the fact and also to show them that extracted honey will granulate, and by so doing proves its purity. Take a sample jar of this honey for exhibition and one to open and let the lady of each house taste the contents, or which is still better, do as Mr. Heddon did—get small widemouthed bottles like the small morphia bottles and fill them with honey and send one to each house-keeper in town, send one to each house-keeper in town, with your compliments, and the price per pound, also where it may be obtained. This is the proper and only way of advertising a town for the sale of honey, and it will pay in every case. The women folks are the ones most generally who cause the sale of honey. One never loses anything by consistent generosity and a little makes a material difference in one's financial receipts.

The distribution of friend Newman's "Honey as Food and Medicine" serves as a good advertisement.

The distribution of friend Newman's "Honey as Food and Medicine" serves as a good advertisement.

The mere placing of your honey on sale at some grocery will not advertise sufficiently, you must sell by sample and by sample only, until you have established a demand for your honey then you may have a headquarters, or put it on sale at each grocery store. If this is done see that each grocer places your article in a conspicuous place, and that he "talks it up." Try to keep your town and vicinity stocked at a reasonable uniform price will do it, provided, you advertise sufficiently.

If shipped away to market there should be no chaff packing used around the honey. Crates holding a single tier of sections, with top-bar down, are the best, as they are less liable to break and not so heavy as to be inconvenient to handle. Ship by freight, and attend to the loading yourself. Load the combs lengthwise to the car or if wagons are used, place them crosswise to the tongue Jars should be shipped in crates with

no packing, but if to any great distance it is preferable to ship extracted honey in the spruce or pine kegs.

These methods of marketing honey

These methods of marketing noney have been used with great success by numbers of ambitious producers and it is evident that a method after this style, along with honesty, is our base for making what we all wish—honey a staple partials.

Noblesville, Ind., Jan. 31, 1884.

We will send sample copies to any We will send sample copies to any who feel disposed to make up clubs for 1881. There are persons keeping bees in every neighborhood who would be benefitted by reading the JOURNAL, and by using a little of the personal influence possessed by almost every one, a club can be gotten up in every neighborhood in America. Farmers have had large crops, high prices, and a good demand for all the products of the farm, therefore can well afford to add the BEEL JOURNAL to their list of the BEE JOURNAL to their list of papers for 1881.

Premiums.—For a club of 2, weekly we will give a copy of "Bee-Culture;" for a club of 5, weekly, we will give a copy of "Cook's Manual," bound in cloth; for a club of 6, we give a copy of the JOURNAL for a year free. Do not forget that it will pay to devote a few hours to the BEE JOURNAL.

#### CLUBBING LIST.

We supply the Weekly American Bee Journal and any of the following periodicals, for 1881, at the prices quoted in the last column of figures. The first column gives the regular price of both:

For Semi-monthly Bee Journal, \$1.00 less. For Monthly Bee Journal, \$1.50 less.

# MANUAL OF THE APIAKY,

#### BY A. J. COOK,

Professor of Entomology in the Michigan Agricultural College.

316 pages large 12mo.; 133 Illustrations.

This is a new edition of Prof. Cook's Manual of the Apiary, entirely re-written, greatly enlarged and elegantly illustrated. The first edition of 3,000 copies was exhausted in about 18 months—a sale unprecedented in the annals of bee-culture. A new edition having been demanded, the present work has been produced with great care, patient study and persistent research. It comprises a full delineation of the annatomy and physiology of the honey bee, illustrated with costly wood engayings—the Products of the Honey Bee; the Races of Bees; full descriptions of honey-producing plants, trees, shrubs, etc., splendidly illustrated—and last, though not least, detailed instructions for the various manipulations necessary in the apiary.

This work is a masterly production, and one that no bee-keeper, however limited his means, can afford to do without. It is fully up with the times on every conceivable subject that interests the apparist. It is not only instructive, but intensely interesting and thoroughly practical.

The following are among the many commendations received by the publisher:

#### APPRECIATIVE NOTICES:

All agree that it is the work of a master and is of all value.— $L^{\prime}Apiculture$ , Paris.

I think Cook's Manual is the best of our Amerian works.—LEWIS T. COLBY, Enfield, N. H.

It appears to have cut the ground from under uture book-makers for some time to come.— Intish Bec Journal.

ls a masterly production, and one that no bee-eeper, however limited his means, can afford to do vithout.—Nebraska Farmer.

Prof. Cook's valuable Manual has been my contant guide in my operations and successful management of the apiary.—J. P. WEST, Wells, Minn.

I have derived more practical knowledge from erof. Cook's New Manual of the Apiary than from my other book.—E. H. WYNKOOP, Catskill, N. Y.

This book is just what every one interested in bees aight to have, and which, no one who obtains it, will ever regret having purchased.—Michigan Farmer.

To all who wish to engage in bee-culture, a manual is a necessity. Prof. Cook's New Manual supplies this need, as it is an exhaustive work.—Herald, Monticello, Ill.

My success has been so great as to almost astonish myself, and much of it is due to the clear, dis-interested information contained in Cook's Manual. —WM. VAN ANTWERP, M. D., Mt. Sterling, Ky.

This book is pronounced by the press and leading bee men to be the most complete and practical treatise on bee culture in Europe or America; a scientific work on modern bee management that every experienced bee man will welcome, and it is essential to every amateur in bee-culture. It is handsomely printed, neatly bound and is a credit to the West to publish such a book.—Western Agriculturist.

This work is undoubtedly the most complete manual for the instruction of bee-keepers which has ever been published. It gives a full explanation regarding the care and management of the apiarry. There is no subject relating to the cultime of bees left untouched, and in the computation of the work P of. Cook has had the advantage of all the previous knowledge of aparists which he uses admirably to promote and make peoplar this most interesting of all occupations.—American Inventor.

It is the latest book on the bee, and treats of both he bee and hives, with their implements. It is of alue to all bee raisers.—Ky. Live Stock Record.

With Cook's Manual I am more than pleased. It is fully up with the times in every particular. I hope the richest reward awaits its author.—A. E. WEN-ZEL, Cullicoon, N. Y.

It is a credit to the author as well as to the publishers. I have never yet met with a work, either French or foreign, which I like so much.—I/Abbe Du Bois, editor of the Bulletin D'Apiculteur, France.

It not only gives the natural history of these industrious insects, but also a thorough, practical, and clearly expressed series of directions for their management; also a botanical description of honey producing plants, and an extended account of the enemies of bees.—Democrat, Pulaski, N. Y.

We have perused with great pleasure this rade merum of the bee-keeper. It is replete with the best information on everything belonging to appending. To all taking an interest in the subject, we say obtain this valuable work, road it carefully, and practice as a dvised.—Ayriculturist, Quebe., Canada.

It may safely be promounced the most complete an comprehensive of the several manuals which have recently appeared in the subject of thees and then handling in a juniers. The studies of the structure of the bee, the different varienes, the various bee products, and following these the points of manufement, extending to the smallest details, are all of high and practical value. Prot Cook has presented the very latest phases of progressive bee-keepin and writes of the themes disensed in the belate his own experience with them.—Pacyfic Raral Press.

bis own experience with them.—Parpic Rical Press
Of the many excellent works which we have examined on bee culture, recently, we consider Prot Cook's the most valuable for the study of those whe contemplate going into the business on he already keeping bees. If thoroughly studied, and its teachings contorned to, by the aparist, who exercises a reasonable degree of common sense, he or she can not fail to achieve at least a reasonable degree of sucress. The large sele of this volume, while evidence of trisic worth, strongly marks the increasing trest which is being token in the management care of bees Promphori the country. The author addresses limiself to the work with a degree of enthusians which carries his reader along with him to the end.—Kansos Farnar.

Pit is printed in the best style of the art, on fine book paper. Price, bound in cloth, \$1.25; in paper, \$1.00, postpaid. Per dozen: cloth, \$12.00; paper, \$9.50.

used, place them crosswise to the tongue Jars should be shipped in crates with

# Books for Bee-Keepers.

Cook's Minnail of the Apincy. Entirely rewritten, grently enlarged and elegantly Hinstated, and is fully up with the Dues on every conceivable subject that interests the quartist. It is not only instructive, but intensely interesting and thoroughly practical. The book is a masterly production, and one that no bee-keeper, however funited his means, can afford to do without. Cloth, \$1,25; paper covers, \$1,00, postpaid. Per dozen, by express, cloth, \$12; paper, \$9.90.

Animy's New Hee-Keeping by L. C. Rnot. The author has treated the subject of hee keeping in manner that cannot full to unterest all. Its style is plain and forcible, making all its renders sensible of the fact that the author's really the master of the subject. Price, \$1.546.

Novice's A BC of Bee-Culture, by A. I. Root. This embraces 'everything pertaining to the care of the honey-bee," and is valuable to beginners and those more advanced. Cloth, \$1,25; paper, \$1.00.

King's Bec-Keepers' Text-Book, by A. J. King. This edition is revised and brought down to the present time. Cloth, \$1.00; paper, 75c.

Langstroth on the Hive and Honey Bee This is a standard scientific work. Price, \$2.00.

Riessed Hees, by John Allen.—A romance of ee-keeping, full of practical information and con-agious enthusiasm. Cloth, \$1.00.

highous enthusiasm. Cloth, \$1,000.

ReceVilture; or Successful Minnagement of the Aplary, by Thomas G. Newman. This pamphlet enthuries the following subjects. The literature of the Aplary - Homey Plants - Queen Rearing Feeding-Swarming Dividing Transfering, Italianizing Introducing Queens Extracting-Quieting and Handling Boses. The Newest Method of Preparing Homey for Market, etc. It is published in English and Gerono. Price for either edition, 40 cents, postpaid, or \$3.00 per dozen.

Food Adulteration: What we eat and should not eat. This book should be in every family, where it ought to create a sentiment, against the adulteration of food products, and demand a law to protect consumers ugainst the many health-destroying adulterations offered as food. 200 pages. Paper, 50c.

The Dzierzon Theory:—presents the funda-mental principles of bee-culture, and furnishes a condensed statement of the facts and arguments by which they are demonstrated. Price, 15 cents.

winch they are demonstrated. Price, 15 cents.

Honcy, as Food and Medicine, by Thomas G. Newman.—This is a pamphlet of 24 pages, discoursing upon the Ancient History of Bees and Honey; the nature, quality, sources, and preparation of Honey for the Market; Honey as an article of food, giving recipes for making Honey Cakes, Cookies, Puddings, Foan, Wines, &c.; and Honey as Medicine, followed by many useful Recipes. It is intended for consumers, and should be scattered by thousands all over the country, and thus assist in creating a demand for honey. Published in English and German. Price for either edition, &c.; per dozen, 50c.

Winterpor Reag.—This approach to experience of the contribution of the

Wintering Bees.—This pamphlet contains all the Prize Essays on this important subject, that were read before the Centennial Bre-Keepers' Association. The Prize-#25 in gold-was awarded to Prof. Cook's Essay, which is given in full. Price, 10c.

Hees and their Management. This pamphlet as issued by the Italian Bee Company, and has had large circulation. The price has been reduced from cents to 10 cents.

The Hive I Use—Being a description of the hive sed by G. M. Doolittle. Price, 5c.

used by G. M. Poolitic. Price, 36:
Kendall's Horse Book —No book can be more
useful to horse owners. It has 35 engrayings, illustraturg positions of sick hoses, and treats all diseases
in a plant and comprehensive manner at that a large
unber of good recipes, a table of doses, and much
other valuable horse information. Paper, 25c.

Chicken Cholern, by A. J. Hill,—A treatise on its cause, symptoms and cure. Price, 25c.

Moore's Universal Assistant contains information on every conceivable subject, as well as receipts for almost everything that could be desired. We doubt if any one could be induced to do without it, after having spent a few hours in looking it through. It contains 430 pages, and 500 engravings. Cloth, \$2.50.

Ropp's Easy Calculator.—These are handy tables for all kinds of merchandise and interest. It is really a lightning calculator, nicely bound, with state and pocket torpapers. In cloth, \$1.00; Morocco, \$1.50. Cheap edition, without slate, 50c.

#### SPECIAL NOTICES.

What is the meaning of 'Dec "What is the meaning of 'Dec. si' after my name on the direction-label of my paper?" This question has been asked by several, and to save answering each one, let us here say: It means that you have paid for the full year, or until "Dec. 31, 1881." "June si" means that the first half of the year is paid for, up to "July 1st." Any other month, the same.

Constitutions and By-Laws for local Associations \$2 per 100. The name of the Association printed in the blanks for 50 cents extra.

Instead of sending silver money in letters, procure 1, 2 or 3 cent stamps. We can use them, and it is safer to send such than silver.

#### Restoring Bees when apparently Dead

REV. L. JOHNSON.

Every person knows that hornets, wasps, yellow jackets, and all the varieties of wild bees will be encased in frost and ice for months, and as soon as warmed and dried will be as active as ever. But the honey bee is not so constituted. Her blood is warm, and her system must be supplied with food to sustain life; yet during winter she lies in a semi-torpid condition, and may even seem entirely dead, and yet be restored. When a boy, I frequently found bees drowned in sugar-water during sugar making, and after they had lain for hours, could be brought to life by lying them in the sun and blowing the breath upon them. In some instances I have them in the sun and blowing the breath upon them. In some instances I have restored them after they had been in water all night. Langstroth states, page 25, that Dzierzon and Berlespech both subjected queens to as much as 36 hours of cold in an ice-house and then restored some of them to life.

restored some of them to life.

The thought occurred to me recently that we might make use of these facts where bees had become starved and chilled in the hive. An opportunity soon occurred. A few days ago, in looking over my hives, I found one which had consumed all their stores, and were all about dead, except between two combs, and these could scarcely move. I immediately gave them some warm

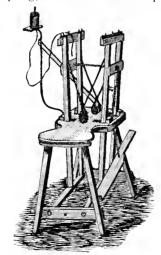

nishing them food, they soon became a small tack. The position the wire is lively. In almost every instance I think now in, is seen in the following cut: lively. In almost every instance I think bees can be resuscitated within 10 or 12 hours after they seem to be dead, unless they become frozen. In examining a hive, if any living bees can be found, if immediately supplied with food and gently warmed, they most likely can be

The last bees to die in a colony are The last bees to die in a cotony are generally those near the queen. Their last feeble morsel is divided with their mother, and oftentimes her position shows she had survived her children some time. Before giving your seemingly dead bees up in despair, make one earnest effort to restore them, and you way he remarked by saving a valuable. may be rewarded by saving a valuable queen and colony.
Walton, Ky., Feb. 10, 1881.

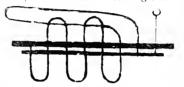

#### Given's Frame-Wiring Machine.

On this page we give some engravings, showing the machine used by Mr. D. S. Given for putting wires in the brood-frames before filling them with comb foundation. He gives the following description of them and how they are to be used:

The two arms seen separated by the springs are regulated by set screws so they will open to a required distance. They are pulled together the foot lever. The upper and lower bars of the frames are punched by pairs, and each arm is made to hold its piece to the exact place by a spring, and are one-half inch apart.

The wire is sewed through both pieces at once by using a harness needle. The wire is run in a Langstroth frame as follows: draw the needle through the first set of holes and return it through

We now place the thumbs in the first two short loops, let up the foot lever, draw in the slack wire on the light spring by the first thumb, and then draw it out on second thumb, and we have all the slack in the centre of the frame, as seen in cut below. Rub over

the wires with the finger, and by the aid of the springs this slack is taken in and enough off the spool to let the frame to its set distance. If the angle wires are wanted, enough wire is broken off the spool to run them in, and the end is fractured on the same factorial with the statement of the statement of the same factorial with the same factorial with the same factorial with the same factorial with the same factorial ways. fastened on the same tack with the other. Then we have the upper and lower bars with the wires, as seen in cut below:

These are piled over the edge of a board, and are ready for use on the

The advantages in this machine speed in wireing, saving over one-half the time. It can be worked by boys as the time. It can be worked by boys as it avoids kinks in the wire, and no danger of having the frame bowed by the wires. Then it is much better suited for lifting off the dies than the solid frame.

#### Upward Ventilation for Bees.

G. M. DOOLITTLE.

On page 42 of the BEE JOURNAL, Mr. F. H. Miner, under the above heading, wholly ignores upward ventilation, and seems to think that "dangerous thing, a little learning," has put stupid theories into the brains of most bee-keepers—for the large majority of our apiarists of the process that force apparents. of the present day favor upward venti-lation. Let us look at the facts and see

the hive with wire hooks and staples, and with a button so arranged that for winter the bottom was allowed to hang suspended an inch below the hive, while

suspended an Inch below the hive, while in summer the buttom was so furned as to bring the bottom board tight to the bottom of the hive, except the entrance. With this hive, father had poor success in wintering bees, while a neighbor wintered his safely with the hive tight at the bottom, and a two-inch auger-hole at the top. Soon after the bottom boards were left fastened to the hives, and a large hole made near the top for the bees to go in and out at, and for ventilation, after which no losses occurred from wintering, of any amount. So much for wintering years ago.

Several years after, father lost all of his bees by that dreaded disease, foul brood, and no more were kept in the family till I purchased again in 1869. At that time there were plenty of bees kept near us in box hives, many of which were set on blocks, as Mr. Miner would have them for successful wintering. We adopted the upward ventilation theory, but not a direct current of air through the hive. Now for the facts again. While myself and four others have about 200 colonies each wintered with upward ventilation every year, not one of the box hive (or lower ventilation) men has a single colony.

Now, I wish to call Mr. Miner's attention to a colony in its natural home in the hollow tree in the woods. Here we find them quite as likely to go into a tree with the hole above the hollow as at the bottom, and those with the hole at the top seem to prosper the best. We also find that the hollow is composed of partially-decayed wood, which surrounds them, and is expelled out each summer by the heat. Thus we have something pointing toward a porous covering for our bees for wintering, from which originated chaff hives, chaff cushions, etc. I also wish to say, his predictions of "great losses this winter from smothering," are all groundless. Bees cannot be smothered in such hives, seal the bottom as tight as you please. With upward ventilation and all air cut off at the bottom, there is no circulation only as the bees themselves cause it, and they make the ci

combs, and these could scarcely move. I immediately gave them some warm syrup, and placed honey on the top of the frames, covering them up. In about half an hour I examined them and found the whole colony active and lively, and they are now as vigorous as any colony I have.

In two other instances, bee-keepers with whom I have talked, have met with the same experience. One stated that he found one colony apparently dead, and frost among the bees, but on placing them in a warm room and fur-

weather, two bees are reared for one old one lost; while in early spring, two old bees are lost to where one young bee is

Now, if Mr. Miner will take five colonies and pack them with chaff according to the best approved methods, stopping all lower ventilation entirely, and take five others, and winter them according to his theory advanced on page 42, I will guarantee that in two years from now he will admit that upward ventilation, through chaff, is the only correct way to winter bees, where wintered on summer stands.
Borodino, N. Y., Feb. 16, 1881.

For the American Bee Journal.

D. LANTZ.

Mr. Epiror:-Please to let us know MR. EDITOR:—Please to let us know, through your excellent JOURNAL, where the seed of the "Rocky Mountain Bee-Plant," and the "Sweet Clover Seed" can be had, and also which of these two seeds will produce the best feed for

This is a great neighborhood for raising pork, and our farmers are making money in the swine culture. But their mode of raising pork differs very much from that of most honey raisers. They do not procure the best breed of swine, do not procure the best breed of swine, and then turn them out to take care of themselves, and find their feed as best they can; and if they succeed in gathering a little surplus, then rob them of it, and appropriate it to some other purpose. But experience has taught the pork raiser that "it pays" to plant and cultivate forty or fifty acres of eorn, at a considerable expense every year, to feed swine. It would, however be considered a wonderfulthing if some of our sidered a wonderfulthing if some of our producers should be told that "it would pay" if they would cultivate only five or six acres of land every year, for the benefit of their bees. This would pay would be regarded as too great an ex-

And then, the farmer that raises pork has not only to give the use of a large amount of land, and cultivate the corn, but he must also gather it, and then sides procuring winter quarters for the swine, must feed them twice or three times every day during the entire winter. This the bee man has not to do, because the bees gather their food, and also feed themselves. And yet we are told sometimes, that bees "won't pay." Neither would farming, or stock-raising, or merchandising, or banking, or any other business pay, if it was man-aged as many manage their bees. Forreston, Ill., Jan. 25, 1881.

The sweet clover is the best, by far. For where to get them, see our advertising pages.—Ed.]

For the American Bee Journal.

#### Bee-keeping in Canada.

WM. F. CLARKE.

It is estimated by those best qualified to judge, that there are about 10,000 beckeepers in Canada. Only a small proportion of these are abreast of the times. The great majority are still in the dark ages of bee-keeping. It is proverbial that nothing is so successful as success. Mr. Jones' exploits have been recorded in our newspapers, and the result is quite a furore in the minds of many, who think they see in the road he has traveled so well, a sure highway to wealth. eled so well, a sure highway to wealth. I receive many letters of enquiry from parties anxious to go into this line of business. It is quite impossible for me to answer them privately, but if the editor of the American Bee Journal ean find a corner for

#### A CANADIAN QUESTION DRAWER,

will try to fill it, and henceforth acknowledge such letters by sending a a postal card to the writers with the legend on it, "Subscribe to the AMERICAN BEE JOURNAL." If present and future subscribers to the JOURNAL will write

a beginning, I will reply to a few letters in this article.

If those I select refer almost wholly to the A B C of bee-keeping, it must not be inferred that all are of this charer, but only that these most urgently call for immediate attention.

#### OLD STYLE BEE-KEEPING.

"We have 45 hives of bees, and have been keeping them in the old fashioned way, that is, in the old box hive, and then after the swarming season is over, put on a smaller box called a 'cap,' on the top of the hive. When a colony does not do well, we smother it and take the honey. Now what I want to know is this—what kind of hive would you suggest?"

Keeping bees in the old box hive is entirely ont of date, and the sooner it is abandoned the better. The difficulty with it is that you cannot regulate the with it is that you cannot regulate the internal economy of a colony, but must leave the bees to do pretty much as they please. Bees need management, the same as cattle, poultry, sheep, logs, or any other kind of farm stock. What profit would there be from any of the live stock of the farm if they were left to themselves? Very little. Precisely so with bees. You must have access to them and control over them or beethem and control over them, or beekeeping will prove a very unsatisfactory business. The main things about a hive are to have it of convenient size, and made on

#### THE MOVABLE FRAME PRINCIPLE.

These two points observed, the simpler a hive is the better. I have tried hives of all sorts and sizes; the result is, that I have found the most compli-cated and costly ones the most worth-less. A hive costing about a dollar, un-painted, and without section frames, or painted, and without section frames, or a dollar and a half, painted or sectioned, is good enough for me, or for any com-mon sense bee-keeper who has an eye to profit in bee-keeping. Such may be ordered as a pattern, and others made from it, or a quantity can be bought in the tlat at a reduced rate and miled to. the flat at a reduced rate, and nailed to-gether by any man who has sense enough to use a hammer.

To adopt a hive of this kind, the bees must be transferred from the old box hives. How to do this is told in the hives. How to do this is tom in the bee books, and no man who keeps 45 eolonies of bees, or a single colony, for that mitter, can afford to do without a good manual of apiculture. The cost of such a book is trifling when compared with its value and utility.

#### BEE-KEEPING AS A SPECIALTY.

"Farming is too hard work for me. must engage in some business that will must engage in some distributed that will keep me out of doors, as my health is not good; therefore I think bee-keeping will be just the employment for me. How long would it take a person of ordinary intelligence to become capable of managing 200 colonies? Of course I intend to the theorems in the colonies of the col micena to study thoroughly books that I will need to make me an expert at the business, but I know I will need a great deal of experience, study as much as I may, before I can become a good beekeeper."

In really to this I is intend to study thoroughly books that I

In reply to this, let my say very distinctly, that bee-keeping is a business which, like any other, demands an ap-prenticeship in order to run it properly. prenticeship in order to run it properly. At the outset, the question should be raised,—have I taste, aptitude and general qualification for it? "Every man can't be a poet," nor can every man be a successful bee-keeper. This question settled, the next thing is to master the principles of apiculture. This can be done by the study of books. Then comes experience, which can only be got by handling bees. As a general rule, it is best to begin bee-keeping with one or two colonies. This does not inone or two colonies. This does not involve much outlay, and if there should be failure at first, as it is very likely there will, the loss is not serious. I cannot say how long it would take a person not say now long it would take a person of ordinary intelligence to become ca-pable of managing a 200 colony apiary. I think if he spent two seasons with a first-class practical bee-keeper he might venture. I also feel safe in saying that if he begins with one or two colonies, by the time they multiply to 200, he will be master of the situation.

er, it might be safe to start on a large farming in general.

#### THE BEE SMOKER.

"Of what use is the smoker, spoken of in articles about bees?

of in articles about bees?"
This enquirer evidently neither owns a manual of apiculture nor takes a beejournal. He will be wise to do both immediately, or sooner. A smoker is used to tame bees, in order that they may be handled easily. It is a pair of small bellows, with fire-box and funnel attached, so made that it can be worked with one hand. Smoke, properly applied, has the effect of quieting the iraseible little insects. eible little insects.

#### FREEZING BEES.

"I wish to know whether bees should be let freeze in winter i

No. They should not even be allowed to get chilled. They should be kept in a temperature a little above the freezing point. Then their natural warmth will point. Then their natural warmth will keep them sufficiently comfortable, and they will relapse into a state of semitorpor, remain very still, consume little food and stand a long winters' confine-ment without inconvenience. This may be secured by chaff-packing the hives out of doors, or setting them in a double walled house, the space between the walls being filled with cut straw, chaff, sawdust or tan bark. In a climate like that of Canada, the space between the double walls should be at least 20 inches. Our winter bee houses failed at first eause the walls were too thin. They did very well in mild winter weather, but when a hard cold spell came, the frost crept through and stayed inside, to the destruction of the bees. Some have had good success by wintering their bees in a dry cellar, but it is not so easy to secure perfect seclusion of light and the desirable quiet in a cellar, as in a house built for the purpose.

For the American Bee Journal

#### Dovetailed vs. One-Piece Sections.

#### JAMES HEDDON.

From the tone of Mr. Riegel's communication in the Bee Journal of munication in the BEE JOURNAL of Feb. 16th, I must think him honest in his opinions about sections. I know, for my own part, that no interest I ever had in any article prejudiced me an iota for or against it. Of course, I give Mr. Riegel the same credit I ask for myself, necessaries with after various his game. more especially after reading his gen-tlemanly and enthusiastic article. It has always been my idea that behind enthusiasm lies honesty, if nothing

Allowing that we are strong believers in the claims we advocate, the next point to settle is the question of who is point to settle is the question of who is right. Mr. Riegel's method is surely a novel one, and I do not see what is to hinder our making the "premium" \$1,000, so long as we risk nothing, and provided the National Convention do not object. I see no reason why they should, unless it depends upon the little pointer of the \$2,000. matter of the \$1,000. But, really, is it not a better test to wait, and see which goes into general use? This will give us the honest decision of thousands of

us the honest decision of thousands of practical bee-keepers, instead of ten "picked" ones. We can remember and wait; can we not?

I do not want your \$10, nor the National Association to have it, without some equivalent. A wager would prove nothing, but to show our earnestness in the matter. the matter. I believe nearly or quite every reader of the BEE JOURNAL will give us credit for that virtue, and we can keep our pocket-books out of this con-

The spruce sections I had reference to are of my own style. Have you used them, Mr. Riegel? I have used only a few of the Root and Lewis & Parks one-piece sections. Now, I wish to say that I have never seen a one-piece section that, when doubled together, the joints did not shut so loosely as to make subscribers to the Journal will write me direct, their communications will receive the promptest attention compatable with other duties. My address is Listowel, Ontario. By way of making life begins with one or two colonies, and can be where the snow touched the wood than strain the thin shaving that held the parts together, which, after a while, and can be was capital to invest, and can be was colonies. If a man has capital to invest, and can be was colonies, a weak, rickety box, or so tightly as to strain the thin shaving that held the parts together, which, after a while, are the case.

If a man has capital to invest, and can be was opposite those parces as was opposite those parces are the begins with one or two colonies, a weak, rickety box, or so tightly as to strain the thin shaving that held the mother parts of the hive. With the parts together, which, after a while, and inclined to think that double hives that was not the case.

If a man has capital to invest, and can objection—or both—at different corners.

er, it might be safe to start on a large cale, but it is with bee-keeping as with arming in general.

He that by the plow would thrive. Himself must either hold or drive."

It is back number, the editor of the BEE JOURNAL said that nailed sections were preferable, because they were stronger than those dovetailed. There are times when combs of honey need are times when combs of honey need the support of a strong section; a sec-tion that will yield \(^1\_8\) of an inch will injure those combs materially at such times. The great majority of one-piece sections have this rickety condition, so far as I have seen them. Again, is it possible to make machine-

ry so true that you can make a one-piece section, or cut pieces to be nailed, so that when squared up into boxes they will be square? I think not; I have never seen it done. The dovetailed boxes can be pressed square instantly.

1 have never seen any dovetail work, except this spruce New England box, in except this spruee New England box, in which the dovetailing was tight enough to make it as strong as nailed. I am not prejudiced in its favor because I adopted it; I adopted it because I was prejudiced in its favor. It is no blood relation of mine, only a child by adoption, and I can east it off any hour and take the one-piece section to my bosom, and I wilk, when I think as Mr. R. does.

A section that is as solid as a nailed

A section that is as solid as a nailed one, and has the advantage of thin one, and has the advantage of thin pieces all around, and the still further advantage that you press it to any angle, right, acute of obtuse, and it is solid the same, is the section "I prefer."

About the "naughty" little sharp corners, "ean you not see them in the above cut? Do you not see how they will snag the caps of the combs next to them? snag the capsof the combs next to them? If separators were used they would not; but if no corners are there they will not, where no separators are used. We cut up three boxes of tin into separators, and watched the effects closely for two years, and these separators are better what determined to the comb supply dealer who two years, and these separators are better adapted to some supply dealer who can "grind" his ax with them. We use them to patch knot-holes, etc. I suppose if the one-piece section was (as it can be) made without the corners (i. e., so the narrow piece would extend elear through), that the warping of the wide pieces would all the worse break the shaving that holds them together. I think, of the two evils, the least one is chosen by putting on the "naughty corners," as shown in the cut.

I have mailed to Mr. Riegel a sample

are that a such as I use, and trust it and time will convince bee-keepers that I am right. If to the contrary, that I am wrong, then I will say, "I was mistaken; that is all."

Dowagiac, Mich., Feb. 18, 1881.

For the American Bee Journal

#### Best Hives for Winter.

#### HENRY ALLEY.

The present winter will demonstrate whether single-wall or double-wall hives are the best for wintering bees on summer stands. I am inclined to the opin-ion that double hives are the best. I have both kinds in use, and as my bees are on the summer stands, I am able to

say which are doing the best.
I examined a few of each the other I examined a few of each the other day. I found that the inner sides of the single hives were very frosty, though the bees and frames were covered with a chaff cushion 4 inches thick; but the bees were in fair condition. Those in the double-wall hives were free from frost, nice and dry. The double hives are exactly like Root's chaff hive, only no chaff is used between the inner and outer walls. This style hive was made by me 15 years ago. I see no need of filling the space between the hives with chaff. A dead-air space is all that is needed. It would seem like nonsense to build a house with walls to feet thick, and leave the doors open during the and leave the doors open during the winter. Now, that is exactly the ease with chaff hives. I further noticed about the single hives, that where the snow was piled against them, the moissnow was pirel against them, the mois-ture condensed there, and considerable more frost was opposite those places where the snow touched the wood than in other parts of the hive. With the

summer stands. The bees in the single hives will fly when it is too cold, while those in the double hives will not. This is owing to the bees having been confined to their hives so long, as they would not attempt to fly from any hive

if confined only a month.

It is nearly three monts since my bees saw daylight until to-day, when they had a good flight. They are all out of doors. This is the hardest winter in all experience for bees-it being two winters in one.

I have made a new double-wall hive, on the Langstroth principle, for wintering bees in on the summer stands, which I may describe in a future article. Wenham, Mass., Feb. 21, 1881.

For the American Bee Journal.

#### Apiarian Melange in General.

DR. J. P. II. BROWN.

Mr. Editor:-In most things I am very conservative—never care to give up an old and tried friend for a new one. If was familiar with the old AMERICAN BEE JOURNAL, from the days of the polished and gifted Wagner. I looked upon it as an old steadfast friend; and when you proposed to change it into a weekly. I received the announcement with anything but favor. I have now received 5 numbers of the "transformed" JOURNAL, which are sufficient to stamp its character. I must congratulate you on your success. In subject matter, in general get up, in neatness, beauty and clearness of typography, the world cantact bartier. not beat it.

Comb Foundation again! After read-

ing our friend John Bourgmeyer's criticism of my article on comb foundation, icism of my article on comb foundation, I felt, perhaps, that I had unwittingly committed what Bro. Clarke terms an "Irish bull." If I did, I can't see it. I discussed foundation, not machines: and I cannot conceive how any one could misapprehend my remarks.

There is no doubt, Mr. Editor, that much newspaper debate could be saved if persons would avoid reading by the rule of distortion, abstain from thinking by the rule of twistification, and stop speaking by the rule of inthation.

by the rule of twistification, and stop speaking by the rule of inflation.

Our winter:—The winter has been the coldest for many years. As bees are wintered out, with no protection, I fear all weak colonies will suffer, and probably die before the 1st of March. Box-hive bee-keepers will lose heavily. Those who use the frame hive can save many colonies by liberal feeding. many colonies by liberal feeding.
Augusta, Ga.

For the American Bee Journal.

#### Size of a Colony of Bees.

E. A. MORGAN.

In the February number of the BEE JOURNAL, E. B. Southwick speaks of my report, and thinks my statement that 3 pecks of bees make a good strong colony, and that my 24 would make that mount a little large. He thinks that colony, and that my 24 would make that amount, a little large. He thinks that bee-keepers generally consider I peck a large colony, 4 quarts a fair colony, and 2 quarts a small one. We might agree, if he had said on the 1st of April; but if he means during the honey yield, I do not agree with him, neither will any bee-keeper who has studied the business and found what it takes to secure a large bee-keeper who hasstudied the business and found what it takes to secure a large surplus. This idea of a colony would ruin beginners; they could never winter a colony, and would never get any surplus. Nothing is more correct than that large colonies give the surplus. This is the essence of all profitable beetween the table beetween the colonies. This is the essence of all profitable beekeeping. I think all successful beekeeping. I think all successful beekeepers will say with me, that I peck of bees is a very small colony, and 4 quarts or 2 quarts are nuclei for queen-rearing, and should be united. If surplus is the object, certainly if hived after June 1st they would not be expected to go into the sections, and would not go into the beet loney-gatherers. I have beheaded many queens because they could not keep up a colony, and have succeeded in getting a race which are profitable. Several of my colonies were worked in 10-frame 2-story Lang-

stroth hives, and filled them with bees from June until frost. Any one of them would measure 3 pecks. They flew in one continuous stream, and a colony such as Mr. Southwick speaks of, could be shaken from 4 frames any time during the season. His frame—12x13 in., 9 in a hive, could hold 28,800 bees, while 50,000 is considered a good colony; thus his large colony is 21,200 bees short of a colony—50,000 dead bees measure 3 pecks. Is have under-estimated, for I think some colonies will reach 60,000 bees. stroth hives, and filled them with bees

think some colonies will reach 60,000 bees.

My plan is to keep prolific queens, which will fill the hive and surplus arrangement full of bees, and then with hard work, constant watching and proper manipulation, we can secure a large surplus. My best colony gave me 245 lbs. of comb honey this season, while the parent colony gave 185 lbs.

I do not think my mode of packing expensive. The outer case is 8 feet of "cull" lumber; the entrance is left open, only one thickness of duck is put over the frames, then the upper story is

open, only one thickness of duck is put over the frames, then the upper story is put on and filled with dry chaff. The gases escape at the bottom, the moisture passes up through the packing, and the heat is retained. My bees, put away as described in the article in December Bree LULYNAL, buye passed through described in the article in December BEE JOURNAL, have passed through the most severe winter ever known in Wisconsin this far, and every one is in the best possible condition, not losing a gill of bees apiece. They have flown for the last two days. If nothing unusual homeons them becaffer Lintend to inhappens them hereafter, I intend to improve upon last year, if possible.

Arcadia, Wis., Feb. 10, 1881.

#### Chips from Sweet Home.

D. D. PALMER.

It is doubtful about there being any plant that will pay to cultivate for honey alone, although there are many which will pay to cultivate for fruit and honey. Which one will pay best, will depend

which one will pay best, will depend upon how the owner is situated.

The raspberry affords considerable honey and blooms with white clover, being of value especially when we have wet weather as the bees will gather honey from it when the rains wash the nectar out of the clover. I have been unable to notice any difference in the amount of nectar yielded by the black, red, or yellow raspberries, there is a difference in the time of blooming, cor-

difference in the time of blooming, corresponding to the time of ripening the truit. Of the yellow varieties, I have not yet found any worthy of cultivation. Of the red, I would cultivate Brandywine for market; it is productive, of uniform size, bright red color and firm, and bears handling well. For home use I would prefer the Turner, as it is a better flavored berry, but too soft to bear handling.

Of the black raspherry there are sev-

Of the black raspberry there are several varieties, the berries of which differ less in flavor than the red; as to which of them is best to cultivate, would which of them is best to cultivate, would depend upon what we wanted them for. The Davidson's Thornless is free from thorns, and is 2 to 3 days earlier in ripening, but of small fruit, and only a few plants will make good strong bushes. The Doolittle ripens within 2 or 3 days of the above, grows upright and stocky, and an abundant bearer of good sized berries; for an early raspberry it is my choice. Lumb's ever-bearer, bears the choice. Lumb's ever-bearer, bears the usual crop, and then continues to shoot up suckers which bear till frost. It is not a profitable herry, for the usual crop is light, and to have a dish of fresh raspberries after all others are gone, you would need a large planting. The Miami and Seneca are good, if we did not have better to fill their place. The Hoosier is a new variety just being introduced, a good bearer of good sized uniform berries of a glossy black color. The Gregg is also new, but more thoroughly introduced than the Hoosier; a good bearer of berries, of uneven size, running from small to very large. For a late bearer, the Mammoth Cluster has

125 bushels per acre, while from 50 to 75 bushels per acre is considered a good yield for other varieties; the berries are uniformly large, and continue so till the last picking. It is a late bearer, from which 2 or 3 pickings can be had after blackberries. The above are all

#### Bee Notes from Mississippi.

OSCAR F. BLEDSOE.

I began the last season with 25 colonies; lost 8 or 10 that "went west;" increased to 76, mostly by natural swarming; have now about 55 colonies. I extracted about 600 lbs. of honey. My error was in allowing them to swarm too much. This season I shall try to error was in allowing them to swarm too much. This season I shall try to repress all swarming, and bring each hive up to the largest capacity, to wit: 2 stories containing 4,000 cubic inches, well filled with bees. I could, with the start I have, easily increase into the hundreds; but as I doubt the pecuniary profit of bee-culture here, I do not desire more than I have at present.

Wintering is easy here. Any hive with a moderate supply of honey, will winter well on its summer stand. It greatly assists wintering, to fill a frame of the lateral dimensions of the top of the live, 2 inches deep, the bottom cov-

of the lateral dimensions of the top of the hive, 2 inches deep, the bottom cov-ered by coarse cloth, with cotton-seed, and set it on top of the hive under the cover. All the honey gathered up to Aug. 1st is of excellent flavor. There is little sale for bees or honey here.

I have received many inquiries from Northern men as to this section. It is good for cotton, corn, wheat, potatoes, fruit, etc. All the hill portions of Mississippi are healthy. Northern men could do well here. All are welcome who propose to help us till the soil or develop the country. Land is chean and who propose to help us thi the son or develop the country. Land is cheap and easily obtained. The best way is to come and look for yourself; make a selection, and send for those left behind. Grenada, Miss., Jan. 27, 1881.

#### Those Stingless Bees.

L. L. LANGSTROTH.

In his prospectus of the "Stingless Bee Association of America," Mr. Haw-ley says:—"On the 15th of September ley says:—"On the 15th of September last, the undersigned published in an Albany newspaper an article on the subject of 'Stingless bees,' which, so far as 1 am aware, was the first intimation the bee fraternity of the United States bad that there existed anywhere on the labitable globe, a species of the honey

haditable globe, a species of the honey bee that had no stingers."

For the benefit of Mr. Hawley and others, who through his ignorance on this matter, may be at much expense, which will result only in disappointmet, L will give you say be fast as to the sting-I will give you some facts as to the sting-less bees of South America.

I will give you some facts as to the stingless bees of South America.

The stingless bees belonging to the genus Melipona, have been long known both in Europe and in this country. Notices of them will be found in works on bee culture. Before the death of Huber, a colony presented to Mr. Judd, of the American Agriculturist, was sent to Mr. Parsons' apiary, at Flushing, L. I., and placed under the care of Mr. Cary, of Coleraine, Mass., who that year had charge of Mr. Parsons' apiary. Mr. Cary told me that they all died after the first cold weather. Their honey was stored in waxen pots shaped like the half of an egg, and entirely separated from their brood combs. Retreating, on the approach of cold weather, to their brood combs, they starved to death. Even with honey stored in brood combs, we find it often difficult in very cold weather, to save our bees; how utterly impossible would it be to do it, if the honey stores were outside of the brood combs where the bees must cluster for warmth?

hollow log in which they were brought from South America. This colony also died as soon as the weather became

died as soon as the weather became cold.

1 believe that Mr. Hawley would be as successful in raising oranges and bananas in the open air where the mercury sinks below zero, as in rearing these bees anywhere in the H. S., Southern Florida perhaps, excepted.

One word more:—"These bees," I quote from Mr. Hawley's circular, "are indigenous to Brazil, south of the equator, inhabiting a climate similar to that of Italy, and with surroundings very like those of that country." Does Mr. Hawley suppose that in Italy, no part of which is exempt from occasional frosts and snows, the climate is similar to that of Brazil?

If Mr. Hawley will refer to the back volumes of the Bee Journal, he will find that before the Italian bees were carried to Brazil, the honey interest there was of small account. The German who carried that bee there, and who, by disseminating it among the natives, after showing what could be done with it, seems to have had no fear or reverence for any or all of the 18 varieties of Brazilian bees described by Mr. II awley. And yet he does not seem to have cirried coals to Newcastle.

I will close by referring to an extract from vol 5, of the Bee Journal, p. 179,

I will close by referring to an extract from vol 5, of the Bee Journal, p. 179, "Bees in Yucatan," which was printed on page 5, of the Journal for this year. Oxford, O., Feb. 21, 1881.

#### Perforated Zinc to Confine Queens.

CHAS. DADANT.

At the National Convention in Cincinnati, Mr. Jones announced that he had made an important discovery. This discovery consists in a sheet of perforated zinc, to prevent the queen from laying in the upper story, or in part of the combs, as well as to hinder the bees from swarping by preventing appears.

the combs, as well as to hinder the bees from swarming, by preventing queens from going out of the hives.

This device was described by its first inventor, Mr. Collin, 16 years ago, in a French book entitled, Guide du Proprietuire d'Abeilles, 1865. I find it also in the French bee journal, L'Apiculteur, for March, 1866, with engravings, Perforated zinc sheets are advertised in two French bee journals and by G. Neigh. French bee journals, and by G. Neighbour & Sons, in every number of the

British Bee Journal.

Although knowing this device for 16 years, I have not presented it to the American bee-keepers, because I con-American bee-keepers, because I consider it as a poor way of preventing queens from laying in the combs destined for the table; for there is more loss of time, for the bees, to cross the perforated zinc, than profit in preventing the queens from soiling a few cells with breed.

with brood.

As to the prevention of bees from swarming, the final result, obtained by the use of this implement, would be the

the use of this implement, would be the killing of the queen by her own bees. Several years ago the lamented Mr. Quinby had invented a queen-yard, to prevent swarming. The queen, who had her wings clipped, was hindered from following the swarm by bands of tin, which were nailed all around the yard, and the bees were compelled to return to the hive.

I tried this device on 14 of my colonies. In 3 hives I saw the queens attempting in vain to follow the swarms, while some angry bees pinched them, as they do the drones when they want to get rid of them. The colony which had tried swarming first, killed its queen at the third attempt at swarming.

As I saw both of the others continue their attempts, with the same violence towards their queens, which they would have killed also, I hastened to satisfy them, by making swarms; then took out all the other bee-yards, never to use them again.

them again.
Of course, the same results would follow the use of these perforated sheets, I therefore advise all the bee papers to copy the above article for the benefit of copy the above arries for the benefit of their subscribers; for the opinion of a man so well known as Mr. Jones, would lead a great many of them to try this obnoxious device, and reap loss and dis-

appointment.

Hamilton, Feb. 7, 1881.

#### THOMAS C. NEWMAN,

EDITOR AND PROPRIETOR,

CHICAGO, ILL., MAR. 2, 1881.

#### Do Bees Puncture Fruit?

EDITOR JOURNAL: The following complimentary notice of the Weekly BEE JOURNAL is condensed from the Lancaster Farmer:

"The Bee Journal enjoys the enviable reputation of having been the first periodical exclusively devoted to apiculture in America, and it is, at this time, the only meekly paper devoted to that specialty in the world! It is a remarkably clean and clear print, and we commend it to our patrons and the public. Each number contains eight pages, well filled with the most ably conducted bee literature in this or any other country. The Weekly will be acceptable to the old patrons of the Bee Journal (and their names ought to be "legion") not only in America, but wherever the English language can be read, or bee culture pursued. And here "The BEE JOURNAL enjoys the en read, or bee culture pursued. And here we would respectfully suggest that so able a specialist as the editor of this Journal should solve the problem, if possible, whether bees do really tear possible, whether bees do really tear open and destroy the pulp of grapes or not. That charge rests upon them here-abouts, whether true or false, and we would like to have the sentiments of those who are able to speak with authority upon this much mooted subject.

The reader will observe the invitation f its editor, for a free discussion, Whether bees injure or destroy sound grapes?" and as the impression prevails in some localities that they do, it is hoped that the subject will receive through the columns of the JOURNAL

the attention it deserves.
Pine Grove, Pa. W. II. STOUT.

The editor would remark that he is unable just now to solve the problem. Many able and experienced apiarists state that they have tested the matter, by placing grapes already punctured before the bees, and when they were busily engaged in sipping the juice therefrom, that they had removed the punctured fruit and put sound grapes in their place; and that in no case did the bees puncture the sound fruit.

On the other hand, many grape-growers assert, as positively, that they do puncture the sound fruit. In some cases, however, they have since admitted that upon closer examination they found the grapes had been previously wounded by wasps or other insects.

The question, then, nust be settled by observation, acute and critical; and we invite those who have witnessed any depredations of this sort to state the matter in the BEE JOURNAL. We do not want theories; but positive witnesses, or physiological reasons why bees cannot commit the offenses charged against them.

We want the facts—whether it be for or against the bees-to ascertain the truth is our only object. If bees can and do commit such depredations, then we must protect our neighbors, or remove our bees to places where they cannot annoy them personally nor destroy their fruit, unless the fact be established that they recompense for all damages, by the timely assistance they render in the fructification of all fruit germs. If they do not, we want to be able to convince our horticultural friends that they are wrongfully charging mischief to the bees.

#### The Law on Food Adulteration.

The following letter on this subject is from Dr. N. P. Allen:

Smith's Grove, Ky I am much interested in the articles adulteration in the BEE JOURNAL. on admeration in the BEE JOURNAL. All consumers are interested in having food adulteration prohibited, and bee-keepers should use all their influence to have such a law passed as soon as possible. We need a general law, to include every kind of adulteration, attaching a heavy penalty, to be divided between the informant and the government. A special law, such as we have in Kentucky, is valueless—a failure. The tucky, is valueless—a failure. The English law, as given in the Bee Jour-Nal, is to the point as far as it goes, but I would have it embrace all commercial articles, for we suffer by the adulteration of almost every artice we purchase.

The enforcement of the law is the difficult portion, hence the necessity of paying the informer liberally for bringing the guilty parties to justice. A sufficient number of chemists should be appointed in every State to analyze articles presented for that purpose, and every thing should be sold under its right name.

N. P. Allen.

"Aye," Doctor, "there's the rub;" these chemists are not above reproachthey too, can be bought or bribed, or are either incompetent or too lazy to make a proper analysis. A case in point occurred in this city only last week. A manufacturer purchased a barrel of honey, and upon finding it granulated. he concluded that it was adulterated. (He had hitherto been using that not granulated.) He applied to a chemist, and that functionary decided (without analysis), that it was about one-half glucose. We were then appealed to and informed the manufacturer that the granulation was of itself proof of purity.

By such indolence, and may we add. ignorance, will not the average chemist often decide contrary to the facts in the case, and thus make the law of no avail: Another case in point occurred in this city during the past month-where an official, by a series of excuses, put off the informant, (for we have a city law against the butter fraud), intending apparently to wear him out, and defeat the enforcement of the law.

It will require the closest scrutiny and the most practical knowledge, to make a law that will be successful in driving to the wall, the unscrupulous adulterators. We must confess we have but little faith in the law before congress, and if passed, we fear that it will prove more of a snare than a blessing.

#### New Publications and Price Lists.

"EXTRACTED HONEY; Harvesting, Handling and Marketing." This is the title of a 24 page pamphlet, by C. & C. P. Dadant, Hamilton, Ill., price 15 cts This gives in detail the methods and management adopted in their apiary. It contains many good and useful hints and is well worth the price.

PRACTICAL HINTS TO BEE-KEEPERS, by Chas. F. Muth, Cincinnati, Ohio; 32 pages, 10 cents.—This pamphlet gives Mr. Muth's views on the management of bees, and embraces several of his essays given at Conventions, &c. It will be read with interest by beginners as well as those more advanced in the science of bee-culture.

THE KANSAS BEE-KEEPER is to be issued monthly by Scovell & Anderson, Columbus, Kan. It contains 4 pages. about two being reading matter, and is evidently intended to wake up an inter- such than silver.

est in bee-culture in that state and sell their supplies. It will no doubt accomplish its mission.

Dr. J. P. H. Brown, Augusta, Ga.—26 pages—Italian and Cyprian Bees, and Apiarian Supplies generally.

This issue of the BEE JOURNAL, the first in the month, goes to all the subscribers of the Weekly, Monthly and Semi-Monthly. Should any of the latter wish to change to the Weekly, they can do so at any time, by paying the difference.

Right glad are we to welcome the Rev. L. L. Langstroth to our corps of correspondents. Having in some measure been restored to health, he immediately grasps his pen, and the article entitled "Stingless Bees," on page 67 of this Journal, is the result. Nearly two years have elapsed since he last wrote, but he knows nothing of the intervening time—hence the repetition of some things found in our remarks in Nos. 1 and 2 of the Weekly BEE Jour-NAL. With his active brain and ready intellect, he will very soon grasp the whole, and catch up.

Can I put in my advertisement once each month and reach all the readers of the BEE JOURNAL?" This is a question that is asked by several. Of course you can. The first issue in every month goes to every subscriber-monthly, semi-monthly and weekly. But as 19 out of every 20 of all our subscribers take the weekly, it is a matter of small moment which week an advertisement is inserted. Those who are too poor to take a weekly, or those who are not enough interested in the art to get and read it, will not benefit an advertiser very much. Advertisements may be inserted every other week, or once a month, or weekly, as desired.

We can supply but a few more of the back numbers to new subscribers. If any want them, they must be sent for

Instead of sending silver money in letters, procure 1, 2 or 3 cent stamps. We can use them, and it is safer to send

Food Adulteration. - The Rural New Yorker, remarks as follows upon the subject:

The adulteration of food, condiments and beverages, has become an immense business from which some people derive respectable profits

Many people would not serious, object to eating oleomargarine, knowing it to be such, but they do object to eating it for butter. When sold as oleowing it for butter. eating it for butter. When sold as oleo-margarine it is well enough, for when properly manufactured it is much more wholesome and nutritious than poor

Pulverized sugar has many properties that would not make it " half so sweet" if we knew what they were. The presence of certain acids is necessary in ence of certain acids is necessary in order to correct the dull, yellow color of the cane sugar, and glucose is now largely used in sugar manufacture; so largely, indeed, in one instance that it is said a single firm in one year realized as profits \$1,000,000 on a capital of \$400,000 (Chucose syrum mixed with learn the color of the color of the said as the color of the color of the said as the color of the color 000. Glucose syrup mixed with low grade molasses makes an excellent golden syrup, which sells well in market, or when allowed to harden it can be ground up and mixed with low-grade dark-brown sugar, and a substance results having the appearance of a refined, light-brown sugar, though not quite as

And so we might go on through the list, finding in confectionery almost every metalic poison known to science; in coffee, various quantities of chicory and other substances; in certain teas, and other substances; in certain teas, 35 per cent of poisonous substances; in pickles, blue vitriol and alum; in pepper, mustard husks, etc., to the extent in an extreme case, of 98 pounds to 2 pounds of pure pepper, and in vinegar corrosive sublimate was found. It is gratifying to know that, in some sections of the country, not only individtions of the country, not only individ-uals but corporations are becoming thor-oughly awakened to this kind of fraud and imposition, and are waging an unrelenting warfare against it, and we trust that at no distant day such pre-ventive means will be used as that no article shall be sold, in quantities large or small, under any other name than its

The next meeting of the N. W. Illinois and S. W. Wisconsin Bee-Keepers' Association, will be held at H. W. Lee's, 2 miles n.w. of Pecatonica, Winnebago county, Ilis., on the 17th of May, 1881.

J. STEWART, Sec.

On account of unfavorable weather the convention at Monroe Centre, Ill., met on Feb. 8, and there being but few present, adjourned to the same place on March 29, 1881.

A. RICE, Pres.

PREMIUMS.—For a club of 2, weekly we will give a copy of "Bee-Culture;" for a club of 5, weekly, we will give a copy of "Cook's Manual," bound in cloth; for a club of 6, we give a copy of the JOURNAL for a year free. Do not forget that it will pay to devote a few hours to the BEE JOURNAL.

Foul Brood, etc.—When the first No. of the Weekly was received I was pretty nearly disgusted with it, for I had taken it so long in the old form that I did not like its shape "one bit," but have become accustomed to it now, and look rather anxiously for its weekly appearance. I at first wondered what a pearance. pearance. I at first wondered what a weekly BEE JOURNAL would do for bee literature of a high character, but I wonder no longer, and I believe it is constantly improving. I am sure I am not the only one that is glad that the "unpleasantness" with the N. E. Convention has been arranged to the satisfaction of all concerned, and hope that vention has been arranged to the satisfaction of all concerned, and hope that you will, in the future, so "mutilate" all personal articles that their sharp edges won't hurt any one. Am glad to see that the bee-keepers are waking up to the importance of that terrible disease, foul brood. Judging from what I know, this region is badly affected by it, and hope by another winter that the bee-keepers in this state will be prepared to see that a bill is passed by our legislature for its suppression. I expect to have the pleasure of showing friend Muth around to see the foul brood in ture for its suppression. I expect to have the pleasure of showing friend Muth around to see the foul brood in Muth around to see the foul brood in this region as soon as the weather is warm enough, and then perhaps you will hear more about it from him. My own bees are, as yet, free from it, and wintering with very little loss. Success to the BEE JOURNAL.

A B MASON

A. B. Mason. Toledo, O., Feb. 21, 1881.

An Excellent Crop.—I started with 50 colonies of black bees last spring; increased them to 110, and obtained 125 creased them to 110, and obtained 125 lbs. of wax and 11,400 lbs. of honey; 10,000 of it being extracted; the balance of it is comb honey cut from Langstroth frames, and put into cans. The honey in this county is nearly all sold, average price 10 1-3 cents per lb.

P. Loucks.
Fresno, Cal., Feb. 14, 1881.

[Mr. Loucks certainly has made an excellent report. Over 200 lbs. of honey to each colony in the spring, and more than doubled in numbers is good enough to satisfy almost any one. We would like to hear further particulars of Mr. L.'s management.—ED.]

Bees Wintering Well.—Bees are wintering very well in this section, even better than usual, although we have had better than usual, although we have had the coldest winter and more of it, than ever experienced in this latitude before. Success to the Weekly AMERICAN BEE JOURNAL. Long may it and its editor live, to give us weekly gleanings from the various parts of the globe.

J. S. TADLOCK.

Kingsbury, Texas, Feb. 3, 1881.

Hope Departing.—'Tis said that misery loves company; we are not philosopher enough to let ourselves down from high hope to low despair without a great deal of jolting. Our bees have been confined 102 days. During the fore part onfined 102 days. During the fore part of last week, hope ran high. True, it snowed. rained, sleeted and about every thing it could, still the snow was gradually going, and we were becoming cheerful. Friday the wind set in briskly from the east, and by evening a genuine blizzard was upon us from the n.e. and shifting to the n. w. we got the grandest snow storm for 23 hours we have had for years. The cars are completely blockaded, no trains since the 11th inst. Bees are from 2 to 6 feet under the snow, and hourly growing more uneasy. We have made it a point to keep them shoveled out; but I shall now have to abandon that; for there is no longer anywhere to put the snow. My bees are all strong, but a majority of them have soiled the entrance more or less, and will perish in consequence of the entrance becoming clogged and the combs breaking down, thereby drowing the bees. drowning the bees. The best success I ever had in wintering was last year, and in spite of the poor summer they averaged 56 fbs. each, and 46 per cent. in-

crease. If Vennor takes away our snow this month, according to contract, I will give him leave to draw upon me for I bbl. white clover honey next fall.

J. N. McColm.
Plymouth, Wis., Feb. 14, 1881.

Ventilation.—I am wintering 90 colonies in the cellar and 7 out of doors; all are living, but some in the cellar are are living, but some in the cellar are getting uneasy. I gave then a small bard snow ball on the top to leak in for water. Mr. Thomas gave the idea in the Journal that it was a good plan in long confinement, but I can tell better after a trial. Mrs. Dawson has lost all her bees; they had no ventilation at the top; the frost accumulated so that water ran on the combs, and the bees drank the water instead of the honey, and when broken open they found ice in the honey-sacs instead of honey, and says that was the cause of death, and you know what a woman can't find out you know what a woman can't find out it is no use for man to look after. L. POINDENTER. Kenny, Ills., Feb 21, 1881.

Bees and Bloom.—Mr. Editor: You misunderstood the first sentence in my letter, published on page 52. I had ref-ference to articles written for, and pubference to articles written for, and published in the JOURNAL. I have always found the AMERICAN BEE JOURNAL ready to encourage everything that tends to the advancement of apiculture in America, and I think, Mr. Editor, you deserve the thanks of all apiarists for your untiring efforts in their behalf. I was much interested in your remarks about graying the flowers to the requires. was much interested in your remarks about growing the flowers to the requirements of the bees. I will give my views in regard to this matter in a future numer of the Journal, if desired. Coleraine, Mass. E. A. Th E. A. Thomas.

[We shall be pleased to have you do so at an early day, to enable spring experiments.—Ed.]

Bees Doing Well.—The past season was very poor for honey here, still we had about as many colonies as usual. Bees that have been properly packed on summer stands are doing well, but those that have been left to take care of themselves have nearly all gone the way of all the earth. I am more than pleased with the present appearance of your Journal.

A. H. Claus.
Rushford, Ill., Feb. 22, 1881.

Albinos and Losses.—There will be a great loss of bees this winter through this section of country. I have lost 5 colonies; among them was one Albino queen that I thought to breed a little extra from the coming season. From a colony of Italian bees which my brother bought 16 or 17 years ago, we reared queens, some of which produced part Albino workers. It is possible from some of these escaping to the moun-tains, originated the first Albino bees tains, originated the first Aidino bees brought to the notice of the public. One thing I am certain of: from a queen reared and sold by me to Mr. Valentine, originated the tinest Albino bees in this state. This queen was bred from a strain of Italians we got from Argo, which, in speaking of, we called the Argostock (wentlened by Valenting in the which, in speaking of, we caned the Algo stock, (mentioned by Valentine in the Jan. number of the Bee-keepers' Magazine), and mated with drones reared from a queen producing part Albino workers.

J. M. C. TAYLOR. orkers. J. M. C. Tay Lewistown, Md., Feb. 9, 1881.

Bees Dying.—The BEE JOURNAL is more than I ever expected it would be in weekly form; it is one of the most useful publications on bee culture, I think, either in the U.S. or Europe. Bees continue to die here very fast. The frame hives were prepared in the following manner: in Oct. the honey boards were removed from the tops of the frames, and in their place was put a nice clean piece of woolen felt blanket, just covering the tops of the frames; on this woolen blanket was put 6 inches of clean wheat chaff, after first putting the cap on. On each side of the cap near the top was a ¾ inch hole, for a free circulation of air, on the north and west Bees Dying .- The BEE JOURNAL is

3 bees could get out at a time. Now after all this fixing, they die very fast, and worse than anything I ever saw so early.

D. W. Flettener.
Languagilla N. Y. Jan 25 1881 Now

Lansingville, N. Y., Jan. 25, 1881.

Come at last.—The long-looked-for time has come at last, when my bees could take a good fly. To-day is the first time my bees have had a good fly since Nov. 5. Bees that were left unprotected are nearly all dead. Some have lost all. My way of wintering is to pack with chaff on the summer stands. Some that I did not work before cold. to pack with chaff on the summer stands. Some that I did not pack before cold weather set in appeared to suffer as much as those left unprotected; those that were packed early, appear to be wintering nicely. I am very much pleased with the Bee Journal. I could not afford to do without ii. I think a person keeping but one colony of bees would be greatly benefitted by reading it.

Frank McCoy. Van Wert, O., Feb. 22, 1881.

Queen Fertilization. - Dr. Love seems to doubt my statement in regard to queens, &c.; as he is favored with a warm climate, he will have an opportunity of testing his proposed plan. Let him test, then report. Not being a medical man, I pass his analysis by. Ninetenths of all the bees in this locality have perished by dysentery. For the first time since Nov. my bees had a flight on the 30th of Jan. I have lost 25 colonies, but there is one consolation. almost every one of them left a rich estate to administer on.

M. B. Fincastle, Ind., Feb. 1, 1881.

Wintering Well.—My bees are wintering nicely. They are packed in chaff on the summer stands. They had a splendid fly yesterday. I wish the Weekly much success. T. W. COLDERT. Smith's Valley, Ind., Feb. 23, 1881.

An English Opinion.—I much admire the energy and enterprise of Americans in apiarian matters, and think they have a powerful exponent in the BEE Journal. F. R. Jackson. London, England, Feb. 12, 1881.

Foul Brood Cure.—By using bromo chloralum, J. M. Blanchard, of Delphos, Kan., effected a complete cure of Foul Brood in its worst form. The mixture Brood in its worst form.

as used by him, was 1 part bromo chloralum, 10 parts water; applied in the usual way.

M. BLANCHARD. Sherwood, Wis., Feb. 14, 1881.

Bees all Right.—Those bees that were in good condition in the fall, and placed in comfortable winter quarters, are now all right. My wife had 11 colonies last spring, increased to 18; Italianized most of them and obtained 500 like of corb back in successful and the second back of the second back o ianized most of them and obtained 500 lbs. of comb honey in sections, but I am bereaved—my wife is no more. She was weakly, and in search of health studied bee culture, and by the aid of the BEE JOURNAL, she was very successful. Now 1 am in charge of the bees, and though sad over the loss of my wife, I shall try to be as successful as she was.

Macon, HL, Feb. 3, 1881.

Macon, Ill., Feb. 3, 1881.

Notes from Otley, Iowa.—I must express my pleasure at the change of the American Bee Journal to a weekly. It is excellent. I await its coming as of an old friend. It is just what we who are engaged in bee culture have long felt the need of. Mr. Young, of Monroe, Iowa, in a letter says: "I still receive the Journal in the form of a weekly, and admire the change very much." We are having a very cold winter. I should think that the ground had been covered with snow for 8 or 9 had been covered with snow for 8 or 9 weeks, with good prospects for its con-tinuing so for some time yet. I think the several methods of wintering bees will be put to the test this winter. My bees are stored away in the cellar where they are warm and dry. I think that I should not deserve to succeed in the business did I have them on their sum-

that he did not care to read it, as he was busy, his bees were dying, and he was becoming disgusted with the business. l did not think this strange. I think I should be about like him, under similar circumstances. Had he been a reader of your valuable Journal, and practiced its teachings. I think no doubt he would have saved several times its cost during the present winter. during the present winter. Success to the Journal. W. C. Nutt. Otley, Iowa, Feb. 5, 1881.

Bees all Dead.—There is not a tive bee in all this county. Out of thousands of colonies I have heard from, not one is alive. Regardless of packing, putting away in cellar, or any other plan of keeping, nearly all die, with plenty of honey in reach, and in my case they had bee candy. The long confinement and cold weather, with not a first rate quality of honey to winter on, has been the trouble.

J. F. CARVER.

Greencastle, Ind., Feb. 12, 1881.

Errata.—On page 573 of the Dec. No. Errata.—On page 573 of the Dec. No. of the Bee Journal, in the communication by L. H. Pammel, Jr., the 11th and 12th line from the bottom of the 2d column, reads "Hoarhound (Salvia officibulis), one of the mint family." Salvia officinalis is the scientific name of the common sage. That of Hoarhound is Magazinian shapes. On page 580 in the common sage. That of Hoarhound is Marrubium vulgare. On page 580, in my report of Nov. 6, in the three last lines, it reads: "all are covered with pieces of rag carpet over the Novice cushion, with cover removed." Cushion should read bee-mat; the mats are made of thin pieces of wood woven together with twine. There would be no sense in untiling carpeting over Novice's sense in putting carpeting over Novice's cushion. Success to the Weekly BEE JOURNAL. J. CHAPMAN. Home, Mich.

Shade for Bees.—I have 18 colonies left, out of 31 that were packed on the summer stands; those that are left seem to be in good condition. Ninetenths of the bees in this locality are now dead. I know several who have lost all they had; some kept as many as 35 colonies; neglect, bad honey and cold weather being the cause. Had the poor honey been extracted, and the bees allowed nothing but sealed honey, and been packed in chaff on their summer stands, losses would not have been half as heavy. I gave sun-flowers a fair trias heavy. I gave sun-flowers a fair tri-al last spring. For shading I planted two plants to each hive; south and west (hives facing east.) As the season ad-vanced, the plants grew very fast, and vanced, the plants grew very fast, and when the heated term came, I had a grand shade, decked with beautiful bloom. I think the Weekly Bee Journal one of the grandest productions of the age.

J. II. THORNBURG.

Winchester, Ind.

## Honey and Beeswax Market.

BUYERS' QUOTATIONS.

CHICAGO.

CHICAGO.

HONEY—The market is plentifully supplied with honey, and sales are slow at weak, easy prices. Quotable at 1842 20c. for strictly choice white comb in 1 and 21b. boxes; at 14g/16c. for fair to good in large packages, and at 1962 12c. for common dark-colored and broken lots.—Chicago Times.

BEESWAX.—Choice yellow, 20624c; dark, 15617.

NEW YORK.

HONEY.—Best white comb honey, small neat packages, I7@18c; fair do., 15@16c; dark do., 12@13; large boxes sell for about 2c, under above. White extracted, 9@10c.; dark, 7@8c.; southern strained, 80@85c.

BEESWAX.—Prime quality, 20@23c.

CINCINNATI.

HONEY.—The market for extracted clover honey very good, and in demand at lic. for the hest, and 3bc. for baswood and dark honey. Comb honey of slow sale at icc. for the best.

BEESWAX—Iss24c.

C. F. MUTH.

SAN FRANCISCO.

HONEY.—We quote comb 12@15c. Extracted, holocywhite, 6%@.7c.; offcolors, 6@6%c.
BEESWAX—22@23c., as to color.
STEARNS & SMITH, 423 Front Street.

W" What is the meaning of 'Dec. SI' after my name on the directionlabel of my paper?" This question has been asked by several, and to save answering each one, let us here say: It means that you have paid for the full year, or until "Dec. 31, 1881." "June 81" means that the first half of the year is paid for, up to "July 1st." Any

#### North-Eastern Convention.

тинко рау.

Convened at 9 a.m., Vice Pres, Doo-little in the chair. After the reading of the minutes, a discussion ensued on Mr. Detwiler's essay, read the first day, and the discussion following it, and it was unanimously agreed that as the controunaninously agreed that as the controversy was not within the bounds of this Association, (New York and the Eastern States), that the whole matter be omitted from the minutes entirely, and not to be allowed to be again brought before the Association.

#### CYPRIAN BEES.

J. H. Nellis read a paper by Julius Hoffmann, of Fort Plain, on "The different races of bees and their crosses." He believed a cross between the Italian and Cyprian bees to be the best. In cross breeding we should consider the drones as of as much importance as the queens, and it will be found that drones are even better for transmitting certain qualities than queens, Mr. Nellis said he had black, Italian and Cyprian bees. The Cyprian is anything but a desirable bee. It is very cross and has no special

bee. It is very cross and has hear merit for honey gathering.

Mr. Root said Mr. Hoffman understood his business, and has made as good reports for years past as almost considerable. Cyprian bees with the construction of the co any other bee-keeper. Cyprian bees are desirable for their continuous breeding, which is almost miraculous. They continue breeding till late in the fall. Italians leave less air between the honey and the cappings of the cells. People who live in buckwheat sections will find

who live in buckwheat sections will find black bees superior to Italians for gathering dark honey.

Mr. House said Italian bees would gather honey from buckwheat when they could get no other, and could get more than black bees.

Mr. Riems said he had between 50 and

Mr. Rians said he had between 50 and 60 queens crossed between Italians and

Cyprians. They were very prolific and gathered honey late in the fall.

Mr. Betsinger favored the Cyprian bees because they were prolific. It is harder to produce bees than it is to reduce the number after they have been produced. That the Cyprians sting more, is in their favor, as they keep away other bees.

Mr. Scofield had found the Cyprians to breed very late in the fall.
Mr. Beebe said he could not see much difference between Italians and Cyprians as to their crossness. Cyprians bred very late in the fall.

 ${
m Mr.}$  Root said Italians were less liable sting than natives, if properly han-ed. He hoped the same would prove

true of the Cyprians.

Pres. Doolittle said Italians did not breed late enough in the fall. He thought the breed could be improved in this respect by crossing with the Cyprians.

#### PURL HONEY.

The Secretary read a letter from Capt. J. E. Hetherington, of Cherry Valley,

Who Wrote:

Our bothstry in the Inture will have to be made profluible to a great extent through the side of extracted homey and that the sale will be made in small packages, and mostly in writer in a candidated condition. If so, a means will have to be taken to dealers who into glucess within Lamintonire that consumers, participarly in the Easten's States, have been constantly told that proof that the mixture they sell by pure less in the fact that it does not get hard or candid; that pure homey never gets build. I have often thought that some little statement covering the fact that pure homey does become randed.

Consumers with the second of this quotity, a major of the North-Pastern Bee Keepe thou, in convention assembled, do assure a second of the second with

Mr. Nellis thought the association would act wisely in adopting a standard of purity. He the resolution. He favored the adoption of

Mr. House said pure honey exposed on implements, re to cold for fom or five weeks, would become granulated or candied.

Most granulated becomes

Mr. Betsinger said the reason for ranulation was not cold but moisture. The moisture was caused by the cold.

Mr. Bacon said it was time that every housewife knew that it was the pure honey which granulated in cold weath-er, and adulterated honey which did not granulate. Granulated honey could be granulate. Granulated honey could be restored to its original state by heating.

Mr. Root offered the following on the purity of honey, which was adopted:

partity of homey, which was adopted:

Secretary G. W. House read an essay on the subject: "Howean we make the apiary the most profitable?"

Mr. Reed thought more attention

should be paid to raising honey produc-ing plants and preserving basswood.

A belated paper on wintering bees, by H. H. Flick was read by Mr. Nellis.
L. C. Root was appointed on the committee on prize essays, to fill the vacancy caused by Mr. Bacon going home.
Mr. Root said it was surprising to him that intelligent has knapper should dis-

MI. 1000 said it was surprising to another that intelligent bee-keepers should object to the trouble of carrying bees in and out of doors in winter. The trouble was of little importance compared with the saving.

Mr. Nellis offered a form of petition to be forwarded to the different mem-

to be forwarded to the different members of the legislature asking for the passage of the law to prevent adulteration of honey and cane sweets, which after discussion, was adopted.

We theundersigned, residents of the — assembly district of the state of Now York, being informed that ability most before the prevention of the adulteration of sugar, syrups, molasses, honey, and similar sweets, now, therefore, we the undersigned heartily approve of such a measure, and respectfully urge the passage of any law that will tend to restrict such adulteration and punish the oftenders. We fully appreciate that such adulterations destroy the tone of legitimate production and ruin the health of volumers it therefore, we as producers and consumers of sweets pray that you give the subject earnest attention and emacused have as shall compel the adulterators of wholes some sweets with compel the adulterators of whole some sweets with compel the adulterators of whole some sweets with compel the adulterators of whole some sweets with compel the adulterators of bale the spanners are the constanting rubble by scriping the polson-decorate the close with their true names, and in the decorate the close with their true names, and in the polson-decorate the close with their true names, and in the polson-decorate the close with their true names, and in the polson-decorate the close with their true names, and the polson-decorate the close with their true names, and the polson-decorate the close with their true names, and the polson-decorate the close with their true names, and the polson-decorate the close with their true names.

### AFTERNOON SESSION.

The report of the committee on question drawer was first taken up. In reply to one of the questions, Mr. Root moved that this convention considers light detrimental to successful wintering; adoptquestions and answers are given below.

In this climate do we have weather cold enough to treeze loves, provided they have honey in the hive to duch they have necess? No. 4s the side box system a success? Yes, by two (no.

Is the side bux system a success 'Yes, by two ; no, by one.

Is a wired foundation a success when used for a broad chamber? No, by two.

Is is advisable to use full sized sheets in broad chamber? Yes.

Which is preferable, a hive without bottom, or bottom fust-ined to hive. Bottom fastened to hive. Bottom fastened to hive.

Is comb foundation a months or a vene old accepted by the bees as readily as that just made? No What amount of surplus room for bey honey by it advisable to give a colony at one time? What the colony requires.

What is the best method of getting bees started in surplus boxes? Fill the boxes with comb.

Would you recommend full sheets of foundation for surplus boxes? One for "bull sheets;" two for "starters".

or surplus boxes? One for "Full sheets;" two for durters." Which it the best, mathral starters or toundation? adural starters

Natural starters

What objection is there to no entre bar in the broad chamber? Does it not make a better whiter communication than being holes through the combs? No confer bur needed.

What is the best quilt for wintering? Anything porous

ortons. Whild is the most convenient arrangement for side ases: "Our own," by two, no side boxes winted

cases. "Our own," by two, no side boxes winted by each.

Will it pay to construct an inner box just large enough to hold, combs to winter 6 Lamestroth or 5 Quinto frames, that will set into the main laye, the object being to carry just what is neoded to the cell har, interest of the main laye. He was also be used for the first of the construction of the cell har, the case of the first layer of the cell har interest of the cell hard the cell hard

us not allipsed? No skeeping the male profitable in a locality swood, with plonty of white clover alsike, find buckwhent? and then patting them in their summer stards the rest of the winter. Be sure all bave hone the fall

#### AWARD OF PRIZES.

Mr. Bosworth, from the committee a implements, reported the prizes

Most print teal box hive awarded to J. H. Nellis
Best smoker, awarded the "New Quinto," made by
L. C. Root & Bro
Best honey rate and hoves, awarded to A. E. Minmin, Bristol, Vt
Best crate honey, to S. Snow, Fayetteville, N. Y.

Best package of extracted honey, awarded to L. C

koot A Bro.
Best display of apiarian implements, awarded to
B Nells
Best comb foundation for the surplus boxes, is
worded to the "Vandervoort foundation," exhibted in J. H Nells
Best comb foundation for the brood chamber,
worded to the "Dunham foundation," shown by C
badant A Son.

All the other kinds are in close competition, and are a credit to the invent-

ors and manufacturers of the same.
Your committee also find articles on exhibition, and call attention othem.

\*\*MIDITIOH, ABU CAH ARUERHIOM O Them.

Bee feeders exhibited by L. C. Root & Bro., A. E. Manim and J. H. Nellis, all worthy of ment, especially the Van Deusen feeder.

A machine for fistening comb foundation in surplus hoxes, by W. H. Mallery.

Peet's conditionation queen cage, by J. H. Nellis, A nest of honey palls by Charles Dadant & Son, Honey, Knives, and Cheshire rakes for supporting omb foundation, while being built out in the brood rames exhibited by J. Schodledd,

W. V. Boswoith, F. H. Cyrexys, O. Dines, Com.

This Secretary offscand, the following.

The Secretary offered the following. which was adopted:

Resolved. That the thanks of this association are ue, and are hereby tendered to the representative of the Utea Morning Herald for the very complete sport of our proceedings as published in that pa-er, and for other courtestes shown us.

The Secretary asked what should be One about prizes for essays next year.

President Doolittle said the medals had brought in essays, but it had shortened the time for debate.

Mr. Nellis thought offering prizes for

essays and implements were progessive. The matter was discussed without action, the subject being left with the executive committee.

#### PRIZE ESSAYS.

Mr. Doolittle, from the committee on prize essay, reported awarding the gold medals and premiums as follows:

Gold medals for best essays: "The

Gold medals for best essays: "The different races of bees and their crossdifferent races of bees and their crosses," J. Hoffman, Fort Plain, N. Y.; "How can we make the apiary most profitable," George W. Honse, Fayette-ville, N. Y.; "Wintering Bees," Chas. Dadant, Hamilton, Ills.; "Marketing Honey," C. P. Dadant, Hamilton, Ills. Cyprian queen offered by L. C. Root for the best essay on any other subject, awarded to W. A. Honse, Fayetteville, N. Y., for his essay on "Foul Brood."

#### SEPARATORS.

Mr. Nellis asked, had any one had any xperience with perforated separators.

Mr. Snow said a year ago he had used arr. Show said a year ago he had used perforated wooden separators, and he found perforated wooden separators were better than tin ones. This season he had replaced his glass and tin separators with with wood. In some cases the bees worked a little faster when wood separators were used.

Mr. Rians said some of the bee-keep-

ers of his section claimed that they got ers of his section claimed that they got whiter honey with wood separators than with tin, the bees clustering on the wood where they would not on tin. Mr. Scoffeld said the warmth of wood

as preferred by the bees to tin or glass. Mr. Betsinger said he had used wood-

en separators some years ago, and his neighbor had tried and abandoned them because he found that bees made many more bars on the wooden separators

har on the tin,

Mr. Doolittle said he had used perforated separators, but came to the conclusion that the cost and trouble did not pay; he therefore abandoned them. He used tin separators, not perforated.

nsed lin separators, not perforated.

Mr. Root said the reason of fastening combs to the side might be due to the weather and atmosphere, and not be due to the fact whether the separator was wood or tin. He had tested wood and tin side by side many times. By using separators of wood the entrances were spread and made larger. The advantage is that the bees will store honey more readily. more readily.

Mr. Snow said that in using tin sepa-

rators he was obliged to put them within 14 inch of the bottom of the boxes, which was about right. By using woodn separators he got his boxes full of

en separators he got his boxes till of bees sooner.

Mr. Root said he had no doubt you could not, by offering Capt. Hetherington \$500 a year, induce him to use entrances less than by of an inch wide.

Mr. Doolittle said his experience was contrary to that of Mr. Root. He did not say the advantage of a larger m.

not see the advantage of a larger entrance. To experiment he took the hottons entirely off, and saw no difference between those with the bottoms entirely off and those with the 14 meh open-1 ing he commonly used.

The convention then adjourned.

## Barren County, Ky., Convention.

The Bee-keepers of this county met The Dee-Reepers of this cominy met at Walmut Hill, Ky., Feb, 12th, for the purpose of organizing a county bee-keepers' society. H. C. Davis stated the object of the meeting, after which Dr. N. P. Allen was called to the chair, and J. M. Holman made secretary, pro-

On motion, the chair appointed the following committees: J. T. Gray, I. N. Greer, H. C. Davls and J. M. Holman, to draft constitution and by-laws, which, on motion, were adopted and the committee discharged.

The convention then elected the following officers for the ensuing year; I. N. Greer, President, J. T. Gray, Vice President, and J. M. Holman, Secretary,

On motion, the president appointed the following committee to select ques-tions for discussion: J. T. Gray, H. C. Davis and D. W. Hodge; after which

the meeting adjourned.

At 1 p. m. the president called the convention to order. The committee on questions reported a programme, which was adopted.

#### WINTERING BEES.

d. T. Gray recommends putting bees in the lower story, covering them with a quilt, filling the top story with old clothes or rags, well covering the hive with straw.

H. C. Davis put his bees in the lower story, put a quilt on, with old clothes or rags in top story; set them on a plat-form, six inches apart, with plank on west side, 8 inches from hive, with grass packed around and under the hive, except the entrance, which faces east; then cover with boards for shelter.

N. P. Allen approved the plans recommended by Gray and Davis, only he did not like the plan of moving bees to a platform, but prefers them to remain on the summer stands, with chaff cushions as absorbents; he said the cushions were convenient, and kept the bees dry and warm, and that it was important to not them down in the lawer story early nut them down in the lower story early in the fall, give them plenty of stores, and arrange the combs so as to have the ones partially filled, in the centre of the hive for the bees to cluster on.

#### BEST PLAN OF BUILDING UP IN SPRING.

H. C. Davis built up weak colonies by

11. C. Davis built up weak colonies by feeding sugar syrup and wheat or rye flour, unholted.

1. N. Greer said he united weak colonies, and fed honey.

N. P. Allen said very weak colonies should be united and fed on sugar sryup, honey or candy, as the season advanced; he would build up the weakest by taking broad from the stronger colonies. ing brood from the stronger colonies. He spread the brood and put combs in the centre of the brood nest, until the lower story was full of brood; continue feeding until honey was abundant in the flowers, and thus raise a large army of bees to gather the harvest when it

Dr. N. P. Allen was made an honorary member.

The following resolution was adopted:

Resolved, By the Barren county bee-keepers, in convention assembled, that the thanks of this society be tendered Dr. N. P. Allen. President of the North American Bee-keepers' Society, for his presence and able advice while we were organizing.

Resolved, That the thanks of this So-

ciety be tendered the ladies of Walnut Hill and vicinity, for the sumptuous dinner furnished on the ground.

On motion, the president appointed H. C. Davis, J. T. Gray and D. W. Hodge a committee to select subjects for discussion at the next meeting, whereupon the committee reported the following: 1st—Which is the lest methnonwing: 1st—which is the best meth-od of increase,—division of colonies or natural swarming? 2d—Which is the most profitable, extracted or comb hon-ey? 3d—The best method of marketing honey?

On motion, the secretary was instructed to have the proceedings of this meeting published in the Glasgow Times and the American Bee Journal.

Adjourned to meet at this place April | 15th, 1881, at 10 o'clock a.m. | 1. N. Greer, Pres. | J. M. Holman, Sec'y.

My Annual Catalogue of Vegetable and Flower Seed for 18ML, rich in engravings from photographs of the originals, will be sent FREE to all who apply. My old customers need not write for it. Fofer one of the lurgest collections of vegetable seed ever sent out by any Seed House in America, a large portion of which were grown on my six seed farms. Full directions for cultivation on ach package. All seed varranted to be both fresh and true to name, so far, that should it prove otherwise, I will refull the order gratis. The original introducer of the Habbard Squash, Phinney's Melon, Marblehead Cabbages, Mexican Corn, and scores of other vegetables. I invite the patronage of all who are anxious to have their seed directly from the grover, fresh, true, and of the very best strain.

NEW VEGETABLES A SPECIALTY. 12m5 JAMES J. H. GREGORY, Marblehead, Mass.

SALISBURY. 1881. J. V. CALDWELL.

## Florida Land--640 Acres.

CHEAP FOR CASH.

DESCRIPTION.—Sec. 4, townsbip 7, south range 7 west, Franklin country, Florida, situated about 50 miles south of the Georgia line, 25 miles west of the city of Tallabases, the capital of the State, and about 25 miles northeast of the city or Apalachicola, a seaport on the Gulf of Mexico, and within 2 sections (5 and 6) of the Apalachicola river; the soil is a rich, sandy loam, covered with timber.

It was conveyed on Dec. 31st, 1875, by Col. Alexander McDonald, who owned 6 sections, including the above, to J. M. Murphy, for \$3,200, and on Sept. 5th, 1877, by him conveyed to the undersigned for \$3,000. The title is perfect, and it is unincumbered, as shown by an abstract from the Records of the county, duly attested by the above at a bargain for cash, or trade for a small farm, or other desirable property. An offer for it is respectfully solicited. Address,

THOMAS G. NEWMAN, 974 West Madison Street, CHICAGO, ILL.

## Books for Bee-Keepers.

Cook's Munual of the Aptary, -Entirely rewritten, greatly enlarged and elogantly illustrated, and is fully up with the times on every conceivable subject that interests the aparist. It is not only in structive, but intensely interesting and thoroughly practical. The book is a masterly production, and one that no bree-keeper, however limited his means, can about to do without. Floth, \$1.25 ; paper covers, \$1.06, postpaid. For dozen, by express, cloth, \$1.2; paper, \$2.3b.

Quinhy's New Work

Onthly's New Bee-Keeping by L.C. Root.
The author has treated the subject of bee-keeping
is a manner that cannot full traintest all. Its style
is the full that cannot have a subject of the fuel that the author is really the master of the
subject. Price, \$1.50.

Novice's A RCof Rec-Culture, by A. I. Root, This embruces "everything pertaining to the care of the honey-bee," and is valuable to beginners and those more advanced. Cloth, \$1,25; paper, \$1.66.

King's Ree-Keepers' Text-Rook, by A. J. King "This edition is revised and brought down to the present time. Cloth, \$1.00; paper, 75c.

Langstroth on the Hive and Honey Ree. This is a standard scientific work. Price, \$2.00.

Blessed Rees, by John Allen.—A romance of bee-keeping tull of practical information and con-tagious enthusiasm. Cloth, \$1.00.

ingious enthusiasm. Cloth, \$1.00.

Rec-Culture; or Successful Management of the Aplary, by Thomas G. Newman.—This pampilet embrees the following subjects: The Location of the receiver of the subject of the Location of the receiver of the subject of the Location of the receiver of the Location of Location

Food Adulteration; What we eat and should not eat. This book should be in every family, where it ought to create a sentiment against the adulteration of food products, and demand a law to protect consumers against the many health-destroying adulterations offered as food. 200 pages. Paper, 50c.

The Bzierzon Theory; -presents the funda-mental principles of bee-culture, and furnishes a condensed statement of the facts and arximents by which they are demonstrated. Price, 15 cents.

which they are demonstrated. Price, 15 cents.

Honey, as Food and Medicine, by Thomas G, Newman.—This is a pamphlet of 24 pages, discoursing upon the Ancient History of Bees and Honey; the matter of the Market; Honey as an article of food, gives the Market; Honey as an article of food, gives receptes for making Honey Cakes, Cookies, Puddings, Poam, Wines, &c.; and Honey as Medicine, followed by many useful Recipes. It is intended for consumers, and should be scattered by thousands all over the country, and thus assist in creating a demand for honey. Published in English and German. Price for either edition, 6c.; per dozen, 50c.

Wintering Rees.—This pamphlet contains all the Prize Essays on this important subject, that were read before the Centennial Bee-Keepers' Association. The Prize—425 in gold—was awarded to Prof. Cook's Essay, which is given in full. Price, 10c.

Rees and their Management. This pamphle was issued by the Italian Bee Company, and has had a large circulation. The price has been reduced from 20 cents to 10 cents.

The Ilive I 1'se-Being a description of the hive used by G. M. Doohttle. Price, 5c.

Rendall's Horse Book.—No book can be more useful to horse owners. It has 35 engravings illus-rrating positions of sick hoses, and treats all diseases in a plant and comprehensive manner. It has a large number of good recipes, a table of doses, and much other valuable horse information. Paper, 25.c.

Chicken Cholera, by A. J. Hill,—A treatise on its cause, symptoms and cure. Price, 25c.

Moore's Pulversal Assistant cootains information on every conceivable subject, as well as receipts for almost everything that could be desired. We doubt if any one could be induced to do without it, after having spent a few hours in looking it through I t contains 480 pages, and 500 engravings. Cloth, \$2.50.

Ropp's Easy Calculator.—These are handy tables for all kinds of merchandise and interest. It is really a lightning calculator, nicely bound, with slate and pocket for papers. In cloth, \$1.00; Morocco, \$1.50. Cheap edition, without slate, 50c.

\$2" Sent by mail on receipt of price, by

J. II. Gregory's Seed Catalogue. J. II. GREGORY'S SEED CATALOGUE. Mr. Gregory's Catalogue (advertised in our columns), opens with several fine engravings of new vegetables, after which follows an immense variety of flower and vegetable seed, including 47 kinds of Beaus, 23 of Beat, 54 of Cabbage and Cauliflower, 26 of Corn, 28 of Cucumber, 28 of Lettnee, 41 of Melon, 17 of Squash, 24 of Tomato, 36 of Turnip, &c., &c., all duly described. Catalogues are advertised free to all.

Constitutions and By-Laws for local Associations \$2 per 100. The name of the Association printed in the blanks for 50 cents extra.

We will send sample copies to any who feel disposed to make up clubs for 1881. There are persons keeping bees in every neighborhood who would be benefitted by reading the JOURNAL, and by using a little of the personal influence possessed by almost every one, a club can be gotten up in every neighborhood in America. Farmers have had large crous high prices and a good bornood in America. Farmers have had large crops, high prices, and a good demand for all the products of the farm, therefore can well afford to add the BEE JOURNAL to their list of papers for 1881.

For the American Bee Journal.

## Do Bees Injure Grapes?

U. E. DODGE.

There seems to be quite a spirited discussion going on in horticultural circles in this part of the country, in regard to the above question, some taking the ground that the bees puncture the skin of the grape, and from the opening draw the juice and appropriate its sweets to their own use; others, that wasps are the first transgressors, and puncture the skin of the grape with their stings, and the bees follow and suck the much-prized fluid from the openings thus made. made.

Now, being something of an apiarist

Now, being sometting of an apparist in a small way, and a grape-grower and market-gardener quite extensively. I naturally feel a deep interest in this question, and if the annoyance continues (i. e., the destruction of grapes in this way in the same ratio it has for the ast two or three years), either the grape-grower or the bee-keeper will have to retire from the contest. Being fully aware that your facilities for acquiring knowledge on all subjects appertaining to the bee and its habits, and ever really to impart that information to the read to impart that information to the read-

to impart that information to the readers of your most exceellent JOURNAL, I should, as a grape-grower and apiarist, esteem it a favor if you put this question to the bee-keepers of America. Prot. Cook, in his "Manual of the Apiary," page 50, tells us that the bee's jaws or mandibles are on either side, just below and at the side of the labrum or upper lip. These work sidewise, instead of up and down as in higher animals, are frequently very hard and share mals, are frequently very hard and sharp and sometimes armed with one or more teeth. Now, this is the same general construction of many of our leaf-eating

not in times of scarcity or total failure not in times of scarcity or total failure of nectar in the dowers, with her industrions habits of utilizing every shining hour, and being provided with such facilities, be tempted to vary somewhat from her natural propensities and encroach a little upon other interests? Our grapes, in all the grape-growing regions of this part of the country, were very hadly injured the not sesson, and very badly injured the past season, and our pets of the hive have incurred the prejudice of the grape-growers against them, especially of those who do not keep bees.

keep bees.

As a grape-grower and lover and admirer of the honey bee, and almost an enthusiast upon its habits of industry and economy, I would not be willing to say a single word against it unjustly, yet I must say that I investigated this subject closely last season, for I was receiving severe injury from this cause, and I saw motions and actions that justify me in saying that I think the bee is tify me in saying that I think the hee is the principal actor in this work of de-struction, and punctures the fruit by a saw-like motion of the head and body, saw-like motion of the head and body, a chafing or rasping motion which ruptures the skin of the grape, and accomplishes the purpose, namely, the skin is ruptured sufficient for them to sip the juices from the interior of the fruit, which is spoiled; it also destroys the market value, and increases the labor in the preparation of the fruit left untouched upon the clusters.

Another thing leads me to this conclusion: the absence of almost all other insects at that season of the year (Senissets at that season of the year (Senissets).

cusson: the absence of almost all other insects at that season of the year (September and October), the most of the insects having gone into a semi-torpid state. Almost all our fruit and vegetable insects do their greatest injury in the earlier part of the season, and in the later months are spun up in their cocoons and numerous other protections for winter ready to emerge in early for winter, ready to emerge in early spring, when warmed by the genial rays of the sun, to prey apon the early and tender vegetation, live a life of luxury and gluttony, return again by their and gluttony, return again by their progeny to the torpid state, and year after year pass through the rigors of winter, generation succeeding generation with searcely a variation.

The wasp theory I cannot believe, from thefact that I do not find one wasp to thousands of bees, and if I did, I would be loth to believe, without occular proof, that they accomplished injury by

would be loth to believe, without occular proof, that they accomplished injury by the sting, for they are possessed of a poison sack, and the mechanical action in stinging is the same which forces the poison through the sting into the object stung, and it is not reasonable to suppose that the wasp would turn around and sip its own venom with a relish, or that bees would follow up and gorge themselves with this poisonous mixture. With the Weekly Bee Journal I am highly pleased. Prof. Cook's "Mannal of the Apiary" I consider a very valuable addition to apiarian literature. Fredonia, N. Y., Jan. 27, 1881.

[Mr. Dodge's point is well taken, in regard to the improbability of the puncture being made by the wasp with its sting. We have frequently seen the damage attributed to the sting of the wasp, but it seemed too unreasonble to and vegetable-destroying insects.

Although the nectar of the flowers may be the natural food of the bee and her delght to gather and store, may she

mischief. Prof. Cook, in his "Manual of the Apiary," page 219, refers to this matter, attributing the work to the jaws of the wasp.—ED.]

For the American Bee Journal,

#### A Fair Crop in a Poor Season.

J. W. PORTER.

The season was a poor one here, as in much of our broad country. Many apiaries in Va. produced no surplus, but in most cases it was the result of bad management. No prudent apiarist will neglect his bees, nor a prudent pomologist his trees, because the season is not to prove remunerative. Such a course leads to sure disaster. As I successful in securing a fair production. succeeded in securing a fair production

in a poor season, it may prove of interest to show how it was done.

Itad I bought good queens for half of my hives that were nearly unproductive, or had I taken time to rear them. I would, doubtless, have largely increased

would, doubtless, have largely increased my production.

Out of 7s colonies in March, I had only six natural swarms and made enough strong ones to keep the number \$4, after doubling up six, I successfully prevented swarming by giving room, and building up weak colonies. As my whole surplus came from 50 colonies, it illustrates the waste by keeping unproductive oneens.

While my best colony produced two strong natural swarms. April 29th and May 6th, the united products of which was 232 lbs., 168 lbs. of it in sections; very many produced no surplus. From the 50 I had 2400 lbs. in sections, and 600 lbs. of extracted, which was sold

ooo ins. of extracted, which was sold for \$460, over freights and commissions. The free use of comb foundation and rapid building up just before fruit bloom, was the secret of such success as I had. It proved to be a great help to have flat-bottom foundations built out in the broad chamber for the secout in the brood chamber for the sections. Some of my bees built out two frames in a night, while others would not touch it, if left in for weeks. In every case the Dunham foundation was every case the Dunnam foundation was taken with avidity. It is surely a grand advance to furnish such foundation at the low rates at which it now is of-fered, but it surely indicates an era of lower prices for honey during our first good season, and we must be prepared

notice the size of sections is still 1 notice the size of sections is still discussed. Bees cannot make as much in 4½x4½ as in larger. I found a decided difference in favor of the larger of the only two sizes I used, 4½x523 and 5x523. It may be caused by the relative diminution of attached surface as well as by its allowing a larger force to work to its allowing a larger force to work to-gether. I use the smaller size to sus-pend in wide frames in the second story and can force bees into boxes to work in them. Cases above brood are preferable when bees will work that way

able when bees will work that way.

I have tried many times, even with full comb sections, but never had the least success in side storing, as recommended by Mr. Doolittle. I have had them remain empty below, with a third story filled, while it was empty in a ten-frame Langstroth hive, that had filled several sections above. "Why is this thus?"

Charlottesville, Va., Feb. 7, 1881.

## Bees Destroyed by Worms.

G. M. DOOLITTLE.

We often read something like this: "Five colonies were queenless, 3 starved and 2 were destroyed by worms." What are we to understand by colonies being destroyed by worms? As we can see no sense in the expression, and as such a statement tends to make the beginner fearful of loss of bees from the ravages of moth worms, we propose to say a few words on this subject, explaining the workings of the larva of the bee moth, and the only fear we need have of it.

Bee Moth or Miller.

In the first place permit us to say, that expressions similar to the above come only from those who are careless or ignorant. From the careless, because

ony from the careless, because they do not attend to their business as they should, so they do not discover that their bees are gone till the combs are destroyed by worms. From the ignorant, because if well posted in all that is going on inside the hive, at all times, they would know better.

We do not propose to tell here what a moth miller is, how she gets her eggs in the hive, how the worms look, etc., for this can be found in any of the books on bees now before the public. It you have not one of these books, our advice would be to get one at once, for you camnot well understand the BEE JOURNAL unless you know the first principles of unless you know the first principles of bee-keeping. Of one thing we are cer-

Male.

tain, that if the combs are not occupied by bees, and have not been exposed to the cold as low as 15 above zero, when warm weather is the rule, we always find the larvæ of the wax moth upon them, and more abundant in those that have had brood in them. When once nave had brook in them. When once under headway, it takes but a short time to reduce the combs in a whole hive to a mass of webs. Now the worms cannot come into full possession of these combs as long as there are bees upon them, although we find here and there worms that long dydad their virillance. a worm that has eluded their vigilance for a time. The Italians keep them out much better than the blacks—a small handful fully protecting a whole hive of

Larry of Bee Moth

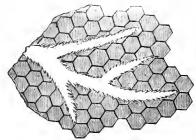

combs, the worms being kept in submission so long as the bees remain. If, from any cause, a colony becomes hope-

lessly queenless, the bees all die of old age in from 50 to 60 days from the time the last bee hatches, if in summer, and as soon as the bees are gone there is no restraint over the worms; thus they have full sway, and in a short time the combs are ruined.

Did the worms destroy the colony?

Did the worms destroy the colony? Certainly not; the colony was destroyed by the loss of the queen, spring dwindling, or whatever the cause was, and the moths came in as an effect. Thus we see that to talk of worms destroying colonies of bees is nonsense.

It frequently happens that we lose a part of our bees in the spring, and wish to preserve the combs till the remainder of our bees increase to occupy them, for such combs are well worth preserving, even in these days of comb toundation. To keep them from being spoiled by the moth worms requires close watching, and all should be looked over as often as once a week, when warm weather comes. As soon as many worms are comes. As soon as many worms are

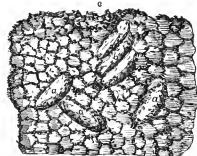

Silk Tunnel of Bee Moth Larver.

found, hang them in a small, close room. found, hang them in a small, close room, so the funces of burning sulphur can penetrate all parts of them, and burn I pound to every 100 cubic feet contained in the room. To burn it, get a kettle, put some ashes in the bottom, put in a shovel of coals, and pour on your sulphur. Shut the door, and leave for 2 or 3 days. If kept from the moth miller it is rarely the case that they will need looking after again; still, we have sometimes had to sulphur again in a month or so.

sometimes nad to supnur again in a month or so.

One more Item: Quinby gave in "Bee-Keeping Explained," that a temperature of 18- above zero, or lower, would kill all life, eggs, etc., of the beemoth. Four years ago we kept some combs in an out-house till February, and the mercury went as low as 15 below zero while they were there. Upon taking them to a warm room and working at them, we found 2 or 3 moth larvae on our bench, crawling. We reported to that effect at the Northeastern Bee-Keepers' Convention that year, but the report was not credited. On the 10th

of this month, when getting our bees of this month, when getting our bees ready to fly by clearing the entrances of dead bees, etc., we chanced to move the entrance blocks to a colony that stood in a bleak place so no snow had lodged around the hive this winter, when we found several moth larvae which possessed as much life as ever, notwith standing their cold nap. Thus we are led to conclude that the worms at a certain stage can stand any amount of ted to conclude that the worms at a certain stage can stand any amount of freezing, for this winter would try their vitality if any would.

Borodino, N. Y., Feb. 25, 1881.

[We are indebted to Prof. Cook for the illustrations in the foregoing article, and which will be found, together with a very able treatise on the natural history and habits of the bee moth, in his "Manual of the Apiary," chapter xix., pages 282–267.—ED.]

The tormer method in a treatment of the tormer method is a way hand. In the former hand is a way hand. In the forme

THE AMERICAN

#### Do We Want the Truth?

REV. A. SALISBURY.

On page 29 of the BEE JOURNAL for Jan. 26, 1881, I find an article from Mr. Boardman. I have no feeling in the matter, but will ask Mr. B. to refer the matter, but will ask Mr. B. to refer to my article again; he will find that it opens as follows: "With the bee-keep-ers of this country it is yet no doubt an important question, whether we shall continue to import bees from Italy." Paragraph 4 reads as follows: "After this subject is thoroughly investigated, this subject is thoroughly investigated, if found to be a step backward to drop the importation of Italian queens, let it be continued with great care, always to get the best Italy affords." Why? Because our American-Italians have been bred up to a high standard of excellence, and we want no "step backward," by importing inferior bees from Italy.

My sole object was to obtain good

importing inferior bees from Italy.

My sole object was to obtain good reasons, if there are any, why we should continue to import from Italy, and that, too, with a very small profit to those who bring them to this country.

My experience with Italian bees, after breeding them almost exclusively for 16 years, is that American-Italians are beter honey-gatherers, and the queens and bees are more beautiful than I have been able to get from the last imported Italians and I baye always tried to get thalians, and I have always tried to get the best, irrespective of cost, having paid from \$5 to \$20 for them. I have made it a rule, where good qualities were developed by the introduction of new blood, to breed from the best.

Always demand the best, whether Aways defining the best, whether home-bred or imported bees, so that the supply dealer will not have to furnish "dark Italians," "leather-colored Italians," and "light-colored Italians"—in ians," and "light-colored Italians"—in a word, all the shades that Italy can afford. Experience teaches that it is the favorable circumstances under which queens are bred, that largely develops beauty in color; and favorable circumstances also produce good qualities. So, we should never be alarmed when we get a queen very highly-colored, if she was bred from excellent stock

Again, do we not run some risk of bringing foul brood from foreign shores? Is not this uncalled for, unless we are as not this uncaned for, thress we are making advance in other directions? At home we can exchange bees with responsible men, and avoid all such risks. I know nothing of foul brood, only what I have read, but if we read it as it is, we be to the man that gets it is his enjoyer. as it is, wo be to the man that gets it in his apiary. As the Cyprian bee is largely an untried bee in this country, but thought by leading European bee-keepers to be a superior bee, we will-ingly take risks for the sake of getting good qualities. Camargo, IR.

For the American Bee Journal.

#### The Practical Use of Foundation.

JOHN F. COWAN.

While I have been deeply interested which have been deeply interested in the discussions on the merits of comb foundation, and though many differ as to the best kind to use, yet I think its importance as a help in building up colninportance as a neigh in building up cononies, and in obtaining greater yields of honey, must be patent to every beekeeper, providing its use can be made practical—i. e., without sagging, breaking down, or killing brood by the improper use of wire.

For the past 2 seasons 1 have been experimenting with the various kinds in use, and have invariably found the Dunham foundation to have the advantage nam foundation to have the advantage in being the most readily accepted by the bees. Concluding this (the Dunham) foundation to be the best, my next desire was for the best means of fastening it into the frames. I tried fastening it to the top-bars as recommended by Mrs. to the top-bars as recommended by Mrs. Dunham and others; I also tried wiring the frames, and pressing the wires into the wax by hand. In the former method I was troubled to some extent with sagging and falling down in the hive, but mostly in the use of the extractor when the combs would break loose from the ten box of the frame and of the fall.

By using the wires as above, I often found rows of empty cells, running parfound rows of empty cells, running par-allel with and above the wires, and found this difficulty arising from the wires not being closely laid in the septum. As I being closely taid in the septum. As I could see no way of obviating the objections in either method, I had become discouraged and almost disgusted with the results, and had determined to abandon the use of foundation entirely, until last season, when my attention was called to the fact that Mr. Given had taken a new departure in the manner of introducing the wires, that is pressing introducing the wires, that is, pressing the foundation in wired frames by the use of a powerful press, which laid the foundation evenly in the septum in such a manner as to render the loss of brood

BEE

I purchased some of Mr. Given's wired I purchased some of Mr. Given's wired foundation, and after giving it the most thorough tests, concluded that I had found the *ne plus ultra* in foundation. We have used in our apiary over 60 lbs. of Given wired foundation, and have yet to find the first larva either killed or removed from the cells. In conclusion, I will say that I consider the essential requisites to a marchical and successful requisites to a practical and successful use of foundation to be a pure article, made from new wax, not lighter than 5 made from new wax, not lighter than 5 feet to the pound, with heavy side-walls and thin septum, secured in the frames in such a manner that it will neither sag, warp, nor break either in the hive or in using the extractor. It has been practically demonstrated to my satisfaction that these results can only be obtained by Mr. Given's method of introducing the wires; and if, by a happy combination, the Dunham foundation could be made and wired by the Given, or a simmade and wired by the Given, or a similar process, the foundation controversy would be virtually ended. Wellington, Ill., Feb. 10, 1881.

For the American Bee Journal.

## The Treatment of Foul Brood.

E. W. FELTON.

In the spring of 1879 I commenced with 21 colonies, and in May, I spread the brood and put in empty combs, once in about two weeks, and in one case put in two empty ones at one time. In August, the one I put the two combs into was badly affected with foul brood, and I saw a few cells of it in 4 or 5 others. That year they had increased to 34 strong colonies. I commenced last spring with 31 colonies and doubled down to 26, and in May I found foul brood in every hive. They commenced to swarm about June 20th, when some of them had not more than 2 pounds of honey in the hive. I sold 5 and increased to 31; and on August 7th I boiled all of my empty hives, and shook 15 colonies into these hives, and put them into the cellar. I boiled those 15 hives, and on the 4th day I shook the other 16 into the clean hives and brought the others out of the ealler. I took what comb they the 4th day I shook the other 16 into the clean hives and brought the others out of the cellar. I took what comb they had made, away from them, gave them whole sheets of foundation, and the 3rd day after, gave the others foundation. They appeared to be fair sized colonies when I shook them off; the day after I gave them the first foundation the apiary was asstill as a grave-yard; there did not appear to be a dozen bees in sight at a time; 3 or 4 came out and clustered on the outside of the hives, and remained there from morning until night, and not a bee stirred, so I thought and remained there from morning until night, and not a bee stirred, so I thought I would try feeding. I boiled some honey and made a tray 1½ by 3 feet, put in it 6 lbs. and put on a float, and when the bees found that, it was interesting to see them take it. They would take the 6 lbs. in 30 minutes. I fed them 80 lbs. and then stopped feeding, and never saw bees try harder to work after that, but they dwindled down to ½ of what they were when I shook them off. By the time the brood began to hatch they had increased to fair sized colonies. On had increased to fair sized colonies. On October 12th I examined them for the last time. I now have them in the cel-

last time. I now have them in the cellar and they seem to be wintering well.

I put the old hives and combs in the cellar and extracted the honey.

I think I made a mistake in not leav-

From the New York Tribune.

## Do Bees Puncture Grapes?

PROF. A. J. COOK.

Not long since I received a letter from Professor F. W. Lustin, of the University of Lewisburg, Penn., stating that the question of "destruction of grapes by these" was expiting attention in their

sty of Lewisburg, Fehn., stating that the question of "destruction of grapes by bees" was exciting attention in their Natural History Society.

More recently Mr. Gustavius Schoenfield, a fruit grower and apiarist of Brockton, N. Y., wrote: "At the last meeting of the Chautauqua County Horticultural Society, war was waged against the industrious bees. My observation leads me to think that the wasps are at the root of the mischief. These latter puncture the fruit, and the aroma from the oozing juice attracts the worker bees, which sip, lap, and suck until nothing remains but the skin and seeds of the grapes. Is it possible for the weak jaws of our bees to tear open the skin of any fruit? This question is a serious one for this section. I tion is a serious one for this section. I lost two tons of Delaware grapes last season. I should say that there were 500 bees to one wasp, but the wasps were always leaders."

Mr. A. G. Gulley informs me that the grapes, especially the Delawares, are greatly injured at South Haven, Michigan. He is not sure but the birds and greatly injured at south maven, incorgan. He is not sure but the birds and the wasps are the prime aggressors, but surely the bees are not slow to join in the attack. Whole clusters of fine grapes are utterly ruined, often not a grape left that is not sucked dry. This is really becoming a most interesting

grape left that is not sucked dry. This is really becoming a most interesting and no less important matter.

At Iluron, Ohio, Mr. II. J. Krock is accused by a bee-keeper, Mr. Peter Klasen, of poisoning his bees by use of Paris green because the bees have become a great nuisance, as claimed by Mr. Krock, in that they annually destroy his grapes, upon which he depends for a livelihood. This has not only led to a serious quarrel but fire-arms have been drawn and expensive litigation began. began.

I have many letters and inquiries like I have many tetters and inquiries like the above. Surely our fruit-growing friends feel, and with no small show of reason, that they are great sufferers. And reason and justice both demand that we as bee-keepers give their com-plaints a most attentive and respectful hearing, and if these complaints are founded in fact, it lies with us not only to make amends but to secure against future injury.

future injury.

I have no personal knowledge that I have no personal knowledge that bees do tear open grapes, though I have sought it carefully and long, both in Michigan and California. That bees will visit punctured grapes to sip the juice, just as they will frequent cidermills in quest of similar liquids, there can be no doubt. Two or three persons have told me that they have seen bees actually tear open grapes. Two of these are extensive grape growers, and were urged by me, two years since, to inform me when they next witnessed such acurged by me, two years since, to inform me when they next witnessed such action on the part of bees. Yet I have not been notified up to date. Several persons have called my attention to such depredations, only to become convinced upon closer examination that the bees merely sipped from such fruit as had been previously wounded.

I have placed punctured grapes be-I have placed punctured grapes before bees, and when the latter got fairly to work sipping the juice, I would replace the wounded fruit by that which was wholly sound, when the bees would at once leave the fruit. So from my observations and experiments I have been led to believe that this habit, if ever true of bees, was exceptional. This opinion was sustained by the well known habit of bees to search out and hap up. opinion was sustained by the well known habit of bees to search out and lap up, not sealed fiquids, but such as were exposed and which were found by the bees, only because of the volatile particles which escaped from them. We do know that wild bees pierce the bases of long tubular flowers, that they may reach the nectar which would else be beyond their reach. I have noticed here for years past that the flowers of the wild Bergamot, Monarda fistulosa, are thus perferated; and more, that the honey bees procure nectar from these openings. If we knew that the honey bees made these openings—I have looked long, but in vain, to find them

thus employed—then we would have something analagous to the tearing open of grapes. From the fact that bees are able to cut away strong paper, and even factory cloth, inclines me to reverse my former opinion that bees, because of their weak jaws, were unable to tear open the tough grape skins. The fact that bees are among the most intelligent of insects, and that by visiting punctured grapes they learn of the presence of the coveted liquid, makes it easy to see how they may have acquired this unwelcome habit, if they do possess it, and may well make apiarslow to contradict their brother

ists slow to contradict their brother po-mologists, who assert positively that bees do puncture sound grapes.

What are we going to do about it? If it be found that our bees do attack and ruin the property of our neighbors, or even of their swarming about the grapes at barvest time becomes an "insuffera-ble nuisance," or even sorely annoving ble nuisance," or even sorely annoying, we should remove our bees to such a distance as will prevent the trespass, or carry them, for the few weeks of the vintage, to a dark cool cellar, from which they are to be removed as soon as the grape harvest is over. As in many places—probably nearly all where grapes are grown—there is a dearth in September, of nectar-secreting bloom, this action may be taken with no loss to the bee-keeper, except that of moving the bees. If the bees can be moved into a more desirable locality for nectar, then the bee-keeper may "kill two birds with one cast of the stone." It is a glad fact one cast of the stone." It is a glad fact that bees only attack such liquids in the absence of the more acceptable flower nectar, so usually there will be no loss from removing to cellar at times when grapes are visited by them. The great drouth the past season in some sections the excessive rain in others, and the consequent dearth of nectar in the flowers, quite probably led to the very numerous complaints the past season.

For the American Bee Journal.

#### How the Bees are Wintering.

M. MAHIN, D. D.

The present winter has been one of the most disastrous to be coulture "with-in the memory of the oldest inhabi-tant." In this section of Indiana apiculture has not made as much advancement as in many other localities, and nearly all winter on the summer stands. and without any special preparation. I am of opinion that two thirds of the bees in Huntington County are already

dead, and the end is not yet.

Mine have fared better than the majority. I had 47 colonies in the fall, and up to this time I have lost 16. The winter has confirmed my previous views in some things, and not in others.

I have heretofore advocated placing r have heretofore advocated placing hives that are to be wintered out of doors in full sunshine, and with the entrance to the south. The results of this winter have strikingly confirmed the correctness of my theory. I had 23 colonies that were slightly shaded by a high paling fense and some fruit trees; they were also partially protected from the west and north winds. I had 24 others standing where they were entirely unprotected from either wind or sun, and facing the south. The average condition of the two lots was the same as nearly as could be determined. They were prepared for winter in the same way, and except in the matter of exposure to the sunshine there was no reason why one should winter better than the other. And now for the result. Of the 23 that faced the north and were partially shaded 11 are dead; and of the 24 exposed to the full sunshine only 5 are dead, and the present average condition of those facing the north is not as good as the others. There were a few days in the months of December and January when the temperature was below 40°, and sometimes when it was scarcely above freezing, that the bright scarcely above freezing, that the bright sunshine tempted the bee to fly. Some of them were lost, but the greater part returned in safety to the hives. Those that perished on the snow would have perished in the hives if they had not come out, as would many of those that returned

returned.
There was another advantage of hav-

ing the sun shine on the front of the hive; the sun warmed the hive so that the bees could get to their stores in the the bees could get to their stores in the long cold weather. I am sure that some of my colonies died of starvation with plenty of honey in the hives, and with from three to five winter passages through every comb. The cold was so intense and so long continued that the bees could not even go through a single bees could not even go through a single comb to get to their honey

The question of absorbents or no absorbents is frequently discussed. My experience this winter does not throw much light on it. The most of my hives much light on it. The most of my hives were covered with four thicknesses of heavy brown paper on the frames, with an inch honey board over the paper. Two had the caps filled with carpet. straw, etc. Of these two, one is dead and the other is in no better condition than those that had no other absorbent than the brown paper. I usually confine my bees in winter below the top bar of the frames by filling the space between the frames with strips of wood, but not so tight but that a little air can escape. I am careful to make passages pe. I am careful to make passages them just below the top bar.

Huntington, Ind., March 1, 1880.

For the American Bee Journal.

### Using Tin Separators.

JAMES HEDDON.

In reply to Mr. Carl Tuttle, in the BEE JOURNAL of Feb. 23, I will say that I succeeded in crating every 5x6 section, succeeded in Graing every 5x6 section, except 16, that I produced in 1879, which number amounted to 2,760. I also glassed a large share of the brightest combs, and no separators were used.

You will remember, Mr. Editor, that the season previous I sold you, at my Glenwood apiary, 80 cases of 5x6 sections, a small part of which were glassed. tions, a small part of which were glassed. You could hardly believe my statement, when I told you that no separators were used next the combs that were not glassed, and that we had only about 20 that were too crooked to crafe. We did use a few separators that season, that were left over from the many that we used the two seasons were left. used the two seasons previous. I agree with Mr. Tuttle, that tin is the best for separators, and that all separators are a great drawback to the production of comb honey.

But to our method: I believe that the honey-board I use, and the clamp method of placing the sections thereon, have something to do with it. Of course, no one would expect to get straight combs without separators, by putting sections within frames, and placing those frames

in a super or upper story.

Now to the  $4^{1}4\times4^{1}4$  sections. I apply these to the hives in a case cut up by divisions, thus—

using no honey-board and no glass. get 99 combs out of 100 straight enough to crate nicely by this method, and I do it by filling each section full of comb foundation. I use foundation which is toundation. I use foundation which is so nicely made that when drawn out and filled, there is no "fish-bone" or other peculiarity to cause one to believe that foundation was employed in its construction. These sections are so small, that when filled with foundation, accurately adjusted, there is almost no rately adjusted, there is almost no chance for the growth of a crooked comb therein. The cover to the case rests bee-space above the narrow tops of the sections, and, as the bees can pass freely around the top-piece of the section. I think that tends to show them where to stoy the learth of sealed! section, I think that tends to show them where to stop the length of each cell. Again, I use a 2 inch end piece, and only a 15% (instead of 134) top and bottom piece to my sections. That, too, tends toward straight combs. It also admits of double capacity for bee passage between the tops of the sections. Because tween the tops of the sections, because it is just wide enough (3%) for two bees to pass at once, exactly opposite each other; 14 inch is not.

I have no fears as to safe transporta-tion and ready sale of honey put up in these I lb. sections, and crated in 12-

comb crates. They come the nearest to being "wheat" of anything I have ever owned in the bee line, unless it be wax; I mean "spot cash." I do not think there will be a very great demand for glassed honey after these packages are well introduced. Besides, the nicest method of glassing is on the outside of the section, with paper caps, a la Moore. In regard to the "proper care of sections, after adjusted," I must confess I have lost the thought that was in my mind when I wrote the article, for when

mind when I wrote the article, for when applied as I have directed, the results are such that no further care is needed,

Dowagiac, Mich., Feb. 25, 1881.

For the American Bee Journal.

## The Wintering of Bees.

J. S. HEAD.

llow to winter bees is important to everyone interested in apiculture, but we have much to learn about handling and wintering bees. Seemingly, to read some works on bee-culture, one would only have to purchase the hive, and then sail (as it were) smoothly along to success—but in reality it is only to encounter "blasted hopes." It requires ability as well as practice to be successful in any pursuit. But do

to be successful in any pursuit. But do not think that I object to any good bee book. For those just embarking, as well as for practical bee men, such are essential; without such, one would soon essential; without such, one would soon fail to realize any compensation for expense and time; of all periodicals my preference is for the Weekly Bee Jour-NAL; and I wish it much prosperity. I will give a more explicit description of the hive I use than that given in Vol.

16, page 473. Have your lumber well seasoned, and nail the hive together; seasoned, and nail the hive together; make some mortar from yellow clay soil, with lime water, adding 1-5 plaster of Paris, and then plaster the inside of the hive ½ inch thick, and in three days the hives will be ready for any reasonable degree of heat or cold, as it is a non-conductor when thus plastered.

If my bees have not sufficient honey in the brood chamber for wintering, I let the upper boxes or frames of honey remain, giving them time to carry it be-

remain, giving them time to carry it be-low and cap it over, for their winter stores. When cold weather begins, remove the frames from the upper story, placing the cloth over the brood frames: pack over them cotton seed, which absorbs all heavy or damp air that may pass through the main entrance or arise from the bees; this keeps them warm and healthy. I have never been troubled with foul brood or dysentery in my apiary; and I have only lost one colony this winter, in that I neglected to pack the seed tightly, and that gave the air too free a circulation through the hive. causing them to chill. I never allow bees to be disturbed, if possible, while in winter quarters. Benton, Mo.

## For the American Bee Journal. Spring Dwindling.

E. A. THOMAS.

With many, spring dwindling has be come a serious drawback to nncessful bee-culture, and how to prevent it is a problem they would like to have solved. Many are prejudiced against cellar win-tering on account of the greater liability to dwindle in spring and I think many are prejudiced against cenar wintering on account of the greater liability to dwindle in spring, and I think, myself, that bees confined through the long winter will have more ambition when they get out in the spring, than those that have had an occasional fly during the winter. But if we can control and direct this ambition, it will turn to our advantage, and this great objection to cellar wintering will be done away with.

Now. I have never been troubled with spring dwindling, and I do not believe anyone need be if they will only watch their bees carefully in early spring, and take every precaution to guard against it. It is of no use to deny that it requires care and trouble to prevent it, and those that cannot give their bees the necessary care and attention must not graphs be or accounting if their if

bees the necessary care and attention must not grumble or complain if their bees do dwindle

Perhaps it will be of interest to the tions.—Ed.]

many readers of the BEE JOURNAL to hear how I manage Orchard Apiary during the early spring months. In the JOURNAL for February 9, I told how I gave my bees water in the cellar and the good results I obtained by doing so. Now, I consider it still more important to give the water after they are taken out in the spring. Bees generally have a sufficient supply of old pollen preserved in honey to last until late in the spring, so their greatest want, in order to carry on broad regring is water and spring, so then greatest mine, in to carry on brood rearing, is water, and by giving it to them 1 manage to keep them quiet, when they would otherwise be obliged to go out for it on cold, windy days and so perish in their zeal for the welfare of the colony. There are a great many cold, windy days when the sun, shining warm on the hive, will cause the bees to come out in large numbers, and the harsh winds soon chilling them, they are unable to return again. On such days I keep them at home by closing the entrance, and shading the hive from the rays of the sun. It will not do to keep bees confined too long out not do to keep bees confined too long out of doors, and just how long is a question that requires good judgment and experience to determine. I have kept them shut up in this way for nearly a week by giving them plenty of water in the hive, but it is seldom that I am obliged to confine them so long.

I would advise every one to go care I would advise every one to go carefully into this matter, and unless they have a good memory, not to attempt it, as a neglect to watch and liberate the bees when it is time may cause their ruin. My hives have glass in the back, by monage of which I go to this to the by means of which I can tell just when the bees begin to show signs of uneasi-ness and so liberate them about as oon as they find out that they would ike a fly. like a fly

Coleraine, Mass., Feb. 1881.

For the American Bee Journal,

#### New Metal Corners for Brood Frames.

W. B. ANDERSON, M. D.

I have devised a plan by which I can I have devised a plan by which I can convert my summer hives into winter or chaff hives, which is quite satisfactory to me, and I think much cheaper and more convenient than any chaff hive I have ever seen. I use a frame the same depth as the Langstroth, and only ¾ as long; they hold 6 1-lb, sections.

Instead of banging a frame on a rablet, as is usually done. I have devised

bet, as is usually done, I have devised a corner-piece made of sheet tin, and bent at right angles to fit the corner of the frame, and on each end of the angles the frame, and on each end of the angles of the corner-piece are projections  $\frac{3}{2}$  of an inch iong, which serve as feet for the frame to rest on, and to give the requisite space at the bottom and ends of the frame. The corner-pieces are  $\frac{13}{6}$  inches long,  $\frac{3}{8}$  longer than the frame is wide, and when the frames are set together the ends of the corner-pieces come in contact, and thus leave  $\frac{3}{6}$  inch space between the frames. When the corner-pieces are fastened to the frames space between the frames. When the corner-pieces are fastened to the frames, stood on end, or sides reversed at pleasure. When the honey season is over and I wish to pack for winter, I have simply to set my frames on end, and pack the spaces thus left between frames and hive with chaff cushions. My hives being high enough for two sets of frames being high enough for two sets of frames give, when frames are set on end, over 6 inches on top, and over 2½ on the sides for packing. Now, I thus get a shallow frame for summer use, and a deep one for winter. Frames are rarely ever glued together with propolis, and when lifted out of the hive can be stood upright on a board without danger of falling, and but little of being blown over. They are convenient for shipping purposes, and, in general, I think a very convenient frame. convenient frame.

I send by mail a sample set of the

corner-pieces, and will send any reader of the BEE JOURNAL a sample set who will pay the postage, etc., and think those who try my plan will like it. Bloomingdale, Mich.

[The corner-pieces have been received and placed in the BEE JOHRNAL Museum, for the inspection of those who take an interest in the later inven-

## THOMAS C. NEWMAN,

EDITOR AND PROPRIETOR,

CIHCAGO, 1LL., MAR. 9, 1881.

Correspondence "and "Letters" having accumulated very much, and it being highly important to give our readers all the news about the present condition of the bees throughout the country, we have devoted much of the present issue of the BEE JOURNAL to these departments, at the expense of the space usually given to Conventions, fully demonstrated that the Weekly BEE JOURNAL was a necessity which could not have been dispensed with much longer. The perfect deluge of correspondence which we now have, could not have been accommodated in a Monthly, and besides, progressive apiarists need a medium of communication much oftener than once a month.

By an oversight in reading proof of advertisement last week, the price of Bingham & Hetherington's honeyknife was placed at \$2. It should have been \$1, as usual.

Sec. Chamberlain, of the Ohio State Board of Agriculture, gives the following as his views on "Bees and honey in Onio:'

" Bees are well distributed through the State. In nearly all the counties, the range, as may be seen, is from 1000 to 3000 hives of bees, with a proportionate product of honey. The total value of the 'crop' is (at 20cts) \$270,548, and bears to the total value of the wheat crop the ratio of \$1 to \$190."

Several bee-keepers in this vicin-y are considering the feasability of holding a convention in Detroit this spring. The law in regard to foul brood, which is about to be passed, makes an organization necessary. It is makes an organization necessary. Tets desirable to know how many would favor the enterprise. Will such please send me their address. A. B. Weed. No. 75 Bagg street, Detroit, Mich.

One of the handsomest publications is the *Hustrated Scientific News*, published by Munn & Co., New York. Every number contains 32 pages, full of engravings of novelties in science and the useful arts. Ornamental wood work, pottery, vases and objects of modern and ancient art are finely

The next meeting of the N. W. Illinois and S. W. Wisconsin Bee-Keepers' Association, will be held at H. W. Lee's, 2 miles n.w. of Pecatonica, Winnebago county, Ills., on the 17th of May, 1881.

J. STEWART, Sec.

TOn account of unfavorable weather the convention at Monroe Centre, Ill., met on Feb. 8, and there being but few present, adjourned to the same place on March 29, 1881.

soon.

## Evils Correcting Themselves.

We are often led to think that all misdemeanors, whether trivial or criminal, possess within themselves a latent corrective principle as well as a retribntive nature. Ancient history furnishes many illustrations of governments becoming so corrupted and lawless that reforms were forced upon the people even before they anticipated them. In Italy, Spain, Portugal and other countries, the enormities of the Inquisition relieved the people from the oppressions of the church; in Russia the magnitude of the system of serfdom became an incubus upon the government itself, and before the many millions of serfs were even prepared for liberty they were declared free; in China and Japan, the Exchanges and Editorial. Time has ignorance caused by a thousand years of seclusion forced the government to take the most active measures for the encouragement of the sciences and arts: the aggressive oppressions of Turkey upon her dependencies finally awakened the resentment of the civilized world, and provoked a salutary interference in her governmental policy; at least twice in the history of France do we find the excesses of her rulers forcing the groaning masses into revolution; and here, in our own country, many of our readers witnessed the presumption and arrogance of the leading traffickers in human flesh, who, not satisfied with a quiet submission to their soul-revolting slavery, insisted upon making all citizens their confederates by the enactment of the Fugitive Slave Law, and thereby broke the chains that bound five millions of humanity in a slavery worse than death.

And who can doubt that commercial abuses will not to some extent correct themselves? It is but a repetition of history, with a different application. For years have we been complaining of the rapidly increasing manufacture of glucose, and arraying a hostility to its imposition upon the public, when now comes the good news that so much competition exists in its manufacture and sale that it is no longer remnnerative. Prices of glucose syrup have rapidly declined from 90 cents and \$1 per gallon to 30 cents, and the marginal profit is so small that there is a prospect of the leading manufacturers drifting into honest trade, and making pure sorghum syr-They will thus become a valuable auxiliary to farmers and producers, and will themselves help to swell the rapidly increasing ranks of those demanding congressional prohibition of poisons under innocent names.

Still another encouraging illustration is at hand in the wayward course of oleomargarine—popularly called "butterine," rightly called "hogine." So rapidly has it been forced upon our market, that the public health has been serionsly impaired by its use, and the many cases of winter cholera have been attributed directly to the uncooked lard employed so largely in its preparation. That which our Congress has been too tardy in legislating upon, and which the dairymen (backed with the enactments of the Illinois Legislature) have been anable to reach, is being rapidly accomplished by the cupidity of the counterfeiters themselves. They have forced We can supply but a few more of the City Council, as a sanitary measure, the back numbers to new subscribers. to prohibit the sale of bogus butter, and If any want them, they must be sent for scarcely a day now passes that arrests of only 2 colonies out of 212, in this the tare not made and heavy fines imposed; severest of all winters.

it has even forced manufacturers and retailers to sell it for what it is. Meantime, continue to condemn adulterations; right will prevail at last, for truly, "There is a God in Israel."

## Be Prepared for Freshets.

At last, after many weary days, and weeks and months of waiting, we have encouragement of mild weather. Hope long deferred, the present winter, has often made the heart sick; and now, that we are about to realize the fruition of our earnest and oft-repeated wishes for warmer weather, it is with a shudder we contemplate the disasters and destruction that will almost certainly follow the return of nature to a normal condition, and the continuance of sunshine for any protracted length of time. The memory of but few, if any, runs back to a winter similar to the present. when the snow (no longer the "beautiful snow") mantled the earth for so many months continuously, and in such lavish quantity. One correspondent wrote us they had enjoyed one hundred and four days of constant sleighing, and since then more than another thirty days have been added. The average and general depth of the snow throughout the entire Eastern, Northern and Western States, has been measurable by feet-not inches. In the Central States the same is true, while in the mountains and on the plains it is without any recorded precedent.

Should a continuous season of genial sunshine follow our unparalleled winter. high waters will prevail for several weeks, but the damage will not be so great to the country at large as if the snow should be carried off with spring rains. Usually, we have had heavy or protracted rains in midwinter which have relieved the earth of its burden of snow, and divided the floods between January and April; but this winter the snow has accumulated, and yet awaits its current to the sea. Therefore, while we hope with our readers for the best, we cannot too forcibly impress upon them to be prepared for the worst. Little rivulets, where usually the sweltering and parched cattle have found scarcely enough water in summer to assuage their thirst, may become rivers in magnitude and pregnant with danger to everything in their proximity; while the usually placid rivers will become mighty torrents, overflowing their banks in many places of comparative safety, flooding the lower country for miles where broad-stretching cornfields have been the rule, and marking their course with destruction and desolation. Our friends in the Central and Southern States along the water-courses, cannot too soon provide for the safety of their families, stock and perishable property. Immediately remove all bees to high. safe ground, then look to the safety of your cattle, horses, hogs and sheep, and have a place of refnge provided for yourselves and the loved ones of home. Be prepared in time-even before this Journal reaches you, the waters may be on their way. We may be unnecessarily alarmed—we hope so, but there is an immensity of snow in the country, and we can see no way for its disappearance except through floods.

Mr. dames Heddon reports a loss

GLEANINGS.

Cause of Dysentery .- Mr. James Heddon gives the following as his views on

"I have observed numbers of dead colonies, and I am more than ever convinced of my previous opinion, that the cause of dysentery is an undue amount of animal or vegetable particles, so to speak, in the honey the bees are wintering on—probably the former— a bacteria that infests honey while in the blossom, or otherwise; that the greatest aggravations of the disease are cold and continement. Cold, because of the more honey consumed, and continement, which prevents the voiding of the poisonous accumulations. Cold and confinement, without this bacteria, will not cause dysentery. These bacteria, withthement, without this bacteria, will not cause dysentery. These bacteria, without cold and confinement, will not show themselves. The above is the only theory 1 can imagine, that will fit all the cases that have come under my observation. 1 believe it, because we so plainly see this great law in the animal and vegetable world, that one life exists at the expense and death of another. Man comes into the category as no exception.

Bingham's Bees.—Our bees had a fine fly on Feb. 22, and are all in fair order; 15 colonies were somewhat out of line, but are sound now. I think they are in but are solud now. I think they are in better order and have wintered better than in 1880. I hear of some who have lost heavily, but have not their exact loss. While it will be sad to hear of the losses, it will be amusing to hear opinions. Bee-keepers are brave, and can face most anything, and not flineh. This winter has shown too many that "in an hour ye think not, the evil is at the door." The past few years had lulled many to repose, and the early frosts overtook them before they were prepared. Enough will survive the winter to demonstrate the fact that bees may be safely wintered in any climate, under favorable circumstances.

BINGHAM. Otsego, Mich., March 4, 1881.

Colonies Strong and Healthy.—As it is thawing and pleasant to-day, my 16 colonies of bees had a good cleansing flight; all are strong but 1, which I am mursing. I have thirty frames of capped honey, what can I do with them?

F. H. SEARES.

Girard, Pa., Feb. 26, 1881.

[Use them for feeding the bees in the spring; hang them in the hive just as they are, or place one flatwise over the frames, and the bees will come up and take the honey very readily. Be careful not to open the hives on cold spring days, or you may chill the brood. It is unneccessary to uneap or extract the honey, the bees will do that.—ED.]

No Surplus. - The Weekly JORRNAL is a very welcome visitor. I put into winter quarters 63 colonies of bees, in winter quarters 63 colonies of bees, in good condition. I put them into a deep, dark cellar, well ventilated, with a temperature of from 45 to 47; while it was, on the ontside, 10 below zero, in the cellar it was 45. I put them in before the cold set in, and I think they are doing splendidly. I obtained no surplus. We had a very late barvest, or there would have been no bees here by this time.

BARTLETT Z. SMITH. Tuscola, III.

What a charming paper is our new Weekly Bee Journal! It is a credit to the country. J. MATTHEW JONES.

All Right,—Last fall I packed my bees with chaff; they are wintering finely; they had a good flight to-day. I am delighted with the Weckly BEE JOURNAL. G. H. ADAMS

North Nassau, N. Y., Feb. 11, 1881.

Why is if?—We have 2 colonies very nicely packed in chaff. Last week, with the thermometer at 45, many of them came out, discharged their feces, and dropped on the snow. We gathered up several, warmed and returned them to several, warmen and returned them to the hive, but they came out again. Others flew off and dropped at a long distance. They had been confined about 14 weeks. What is the cause? ROBERT 11. SMITH. Faulkenburg, Ont., Feb. 14, 1881.

[They had contracted dysentery from long continement, and came out of their hives to die, which would have resulted had they remained in. The loss to the colony will hardly be perceptible, if those remaining are healthy.—ED.]

Italians vs. Blacks for Wintering. The loss of bees here is over 150 colonies, there not being more than a dozen left. The loss was mostly caused by poor, unsealed honey and long confinement. The winter has been unusually severe. The past 2 years were poor for bees, especially the last. I had but 2 swarms and obtained 400 lbs, of honey from 23 colonies last year; and now I have only 8 left out of 24. I use the Quinby hive packed with chaff; but like the Langstroth frame best, as it is more easily handled. The black bees more easily handled. The black bees are nearly all dead; of 12 black colonies I have only I left; out of 12 Italian colonies, 7 are alive. I hope to get some of the best strains in the country, and build them up again, as I have plenty or combs on hand. The BEE JOURNAL is a welcome visitor.

CHARLES F. UPHAUS. Batesville, Ind., Feb. 18, 1881.

Shallow Hives for Winter .- I went into winter quarters with 14 colonies (13 blacks), 12 were in Langstroth and simplicity hives, 2 in box hives; 10 colonles had sufficient stores; 2 were weak. The cold spell in Nov. caught me unprepared, to some extent, although all but 2 in Langstroth and simplicity hives, had 7 inches of chaff covpacked the 12 with dry straw on all sides but the front, and covered them so that the straw would not become wet. Nine lived through the second cold wave, but now 8 more are dead; all left plenty of stores, so that so far, I have lost 11 out of 13, and 1 that is now livlost II out of 12, and 1 that is now living was shipped by rail 25 miles, on Dec. 15, in a tall box hive. All the bees in this neighborhood in Langstroth hives are dead, while, as far as my knowledge goes, those in tall box hives are living. Now why is this? Do you not consider the Langstroth hive too shallow for wintering, especially in severe winters like this? I am more than satisfied with the Weekly BEE JOURNAL.

J. H. EBY.

North Robinson, O., Feb. 28, 1881.

[The deep frames, as also the shallow ones, have their ardent admirers, and all claim especial advantages for their favorite hives. With everything favorable, we cannot imagine why one should be preferable to another; in other words, the most successful hive one winter often proves most disastrous the next. Could we regulate the winters, it would be an easy matter to determine the proper depth of frames.—Ed.]

Bees in Good Condition.-We are having one of the most severe winters, that we have had in this part of the world for many years; in fact its equal is only remembered by the oldest settlers. On Feb. 3d the thermometer stood 30-below zero. Last winter our coldest weather only reached zero. Our bees have been confined since the 5th day of Dec. until the 11th day of the present month, making in all 67 days, or a little over nine weeks. A part of our hives which stood in a row near a fence, was completely [—ED.]

drifted out of sight; the rest were only partially covered with snow. Since the thaw, it has been quite cloudy, the thermometer being at 17 above zero; some of the bees flew quite briskly, but the most of them were rather inclined to remain quiet. As far as we have examined we find them in very good condition; nuch better than we expected tion; much better than we expected. A few show signs of dysentery, though not to a bad extent. There are quite a number of beginners in this vicinity, with only 6 or 8 colonies each, that have lost a number of colonies; undoubtedly fost a number of colonies; indoubledly the cause was a lack of proper protection for winter. But perhaps the "winter of our discontent" may come during the cold, stormy blasts of March; but it is to be hoped they will come out all right.

V. H. Ormsby.
Pierpont, O., Feb. 14, 1881.

Bee Dress for a Girl.-My father has long been a bee-keeper, and proposing to assist him the coming summer, I defor a most suitable bee dress for a girl, in regard to material and style of making.

Bell Tomlinson.

Allegan, Mich., Feb. 20, 1881.

[In answer, we copy from Prof. Cook's "Manual of the Apiary, page 197.—Ep.]

" For ladies, my friend, Mrs. Baker, recommends a dress which, by use of the rubberskirt-lift or other device, can be instantly raised or lowered. This will be instantly raised or lowered. This will be convenient in the apiary, and tidy anywhere. The Gabrielle style is preferred, and of a length just to reach the floor. It should be belted at the waist, and cut down from the neck in front, one-third the length of the waist, to permit the tucking in of the veil. The under-waist should fasten close about the neck. The sheaves should be onite the neck. The sleeves should be quite long to allow free use of the arms, and gathered in with a rubber cord at the wrist, which will hug the rubber gauntwrist, which will nug the result of arm, and prevent bees from lets or arm, and prevent bees from the sleeves. The pantalets should be straight and full, and should also have the rubber cord in the hem to draw them close about the top of the

No Flight since November.—My 30 colonies of bees have had no flight since Nov. 1, and I fear they need it very much—a part of them being "packed" on the summer stands, while the rest are in the cellar. The Weekly Bee Jour-NAL never comes before I am ready for its valuable instruction. A do not see how I could get along without it. I wish it every success. II. II. MITCHELL. Maquoketa, Iowa, Feb. 28, 1881.

Bees in Missouri.—Is it possible to transmit foul brood in foundation? I have been using it to some extent, and expect to use it more extensively in the spring. We have had a long, cold winter; bees have had but one good fly since Nov.; about the 5th of Feb. they had a partial fly. I think fully one half of the bees in the country will die. The thermometer has indicated 18 below zero. A poor season, with an enormous fruit crop, is, perhaps, the cause. My bees appear all right; they are all well packed in chaff. My neighbor's bees are in moderately good American hives, without protection, except open honey-boxes on top, and they are all right. So I do not know which method is best. I know of no other bees packed in the country, but hundreds are dead; percountry, but hundreds are dead; perhaps packing would have saved some. Linden timber is plenty with abundance of white clover, and a perfect sea of fall flowers, at the head of which, as a honey producer, stands the Spanish needle. The so-called "Simpson honey plant," grows wild, but not in sufficient quantity to be of much benefit, only to show that it is a favorite with the bees, from daylight until dark. Buck-wheat does not amount to dark. Buck-wheat does not amount to much here: it often fails to secrete honey. I shall, this summer, try alsike, white, and melilot clovers.

A. R. LEEPER.

Odessa, Mo., Feb. 28, 1881.

[Foul brood will not be transmitted by the use of comb foundation, even if

Granulation of Honey.—I should like to know Mr. Hoge's plan for keeping honey from granulating. Heating honey makes it darker, and if it boils it spoils the flavor. Please give it in the BE JOURNAL. G. F. NORTHROF. Southport, Conn., Feb. 10, 1881.

IWe know nothing more of his plan than that given on page 37. Perhaps he will give it in some fufure number of the Journal.-Ed.]

Wintering in Maine, -- I fear it is too far north here in Maine to winter bees on the summer stands. In winter-ing in the cellar the combs get moldy. Mr. Root advises wintering on the summer stands, and I have tried it for two seasons. Last winter I put my weakest colonies into the cellar, but more perished of those on the summer stands than those in the cellar. This winter I have 0 in the effect of the seasons. have 9 in chaff hives, 12 in tenement hives, 4 in house packed with chaff and straw, 6 in dry goods boxes stuffed around with straw, and 23 in the cellar with chaff cushions over the frames, and chaff division boards.

Dexter, Maine. L. FRENCH.

Queen Rearing.—Mr. Weed, on page 58, of the Bee Journal, asks how many colonies I made yield \$25 each, at queen rearing. It was fifteen colonies. Perrearing. It was fifteen colonies. Perhaps I ought to explain that all of the income was not derived from queens, as there were eighteen colonies sold in the fall, and I had 600 lbs. of extracted honey, but the rearing of queens was my specialty, and the main income was from this source. Judging from my experience, I think I could care for 40 colonies, depends of a green varying. experience, I think I count care for we colonies, devoted to queen rearing. More time, per colony, is required in queen rearing, than in working for honey, but I think queen rearing pays, in the long run, a little the best.

W. Z. HUTCHINSON,

Porgraville, Mich.

Rogersville, Mich.

Death!! Death!!! Death!!!--I have long since found that it is not best to "whistle until out of the woods." I am out, and no mistake; but I have not a single bee left. My bees had plenty of honey. I had a very small increase, of honey. I had a very small increase, and that by natural swarming; but my bees were not strong in the fall. There was something the matter with them last summer. From July on, thousands last summer. From July on, thousands of young bees came out of the hive as though they would start for the field, pitch off of the alighting board to the ground, and make a few attempts to rise, and then turn on their backs and die. They would act just as though they had been stung. Sometimes the ground was covered with bees in front of the hive, for several hundred yards. I had just Italianized them; but now the bees in the county are nearly all gone, there is nothing left to build up with. I weighed my bees on the 1st of Nov., and marked the weight on the hives. and put them into winter quarters on the morning of the 15th, and they never lived long enough to eat more than 2 lbs. of honey. The walls of my winter lbs, of honey. The walls of my winter bee-house are 12 inches thick, filled with dry sawdust. I had 18 colonies in this place, and I packed in sawdust out of doors, and there was but one colony alive by the 1st of Feb., and they died before the month was out. I think it is safe to say that 24 colonies out of every 25 are dead, in Randolph Co., 1nd. I will try again. I love bees and the

BEE JOURNAL. ABE HOKE. Union City, Ind., March 4th, 1881.

Five per cent. of Loss.—My loss is 5 per cent. up to date. I have not lost one that was packed. The loss will not vary much from 20 per cent, by the 1st of May, and one half to those with no protection. The January thaw, that came February 10, has saved my bees. Mr. Betsinger hit the nail on the head whom he wild: "No honey plenty of when he said: "No honey, plenty of foul brood; plenty of honey, no foul brood." I hear complaints from Mich., of "no honey, and of foul brood" mak-The long and the short ing sad havoe. The long and the short of it is, that in a poor season it will spread fast; and in a good season, it is early cured by cutting out with a knife.

W. L. Congshalla West Groton, N. Y., Mar. 3, 1881.

Losses in the Cellar. - Live bees are a scaree article here, and will be more so if winter continues much longer. Many persons have lost all, while none have escaped without considerable loss, 1 am often asked the question: "What is the cause of the great loss of bees?" I cannot give a satisfactory answer. The continued excessive cold weather is probably the main cause. In one cellar that I know of, bees have, for several years, wintered well. This winter all have died except 1 colony, and that is quite weak. They were put in after the first cold snap, and were pit in after the first cold snap, and were strong and ap-parently in good order; all were well supplied with honey. At first I did not like the change from monthly to weekly, but am well pleased now.

ISAAC SHARP.

Waveland, 1nd., Feb. 23, 1881.

Duplication.—The linest queen I have came from D. A. Pike.—She is light in color, and prolific, and produces the linest marked workers that I ever saw. She does not duplicate her bees: they are very fine. They do not duplicate, and never will.

A. J. TUNNELL. Carrollton, Ills., Feb. 23, 1881.

Sad loss of Bees.-In this vicinity nearly all the bees are dead, caused by nearly an the bees are tead, caused by neglect in preparing for winter. Some have starved for lack of stores, but many died with plenty in their hives. Mine are packed in chaff on the summer stands, and are yet in good condition.

H. B. BRITTAIN.

Alexandria, Ind.

Will soon be ready for the Harvest.-My bees are never moved from their summer stands, and out of over 80 colonies I have only lost 4. They have had a severe time, but as soon as they are ready to go to work I shall give them from grand ready.

them fresh ground rye-meal. E. C. JORDAN. Stephenson's Depot, Va., Feb. 22.

Highly Pleased.—Your neat and very desirable Weekly BEE JOURNAL I read through as soon as it comes. I am highly pleased with it, and rejoice that we are, through your foresight and generosity, to have the pleasure of greeting your valuable JOURNAL four times each wants. A. W. HALE.

Three per cent. of Loss.—Last fall I put 35 colonies into winter quarters. They were in Langstroth double-walled hives, packed with chaff on the top, bottom, and on three sides. I have lost but 1 yet, though they did not have a flight from early in Nov. untilFeb.11. Yesterday I looked over 3 colonies, which I found strong, having a little brood, and honey enough to last them until the middle of April, when I shall have to feed them. Losses are very heavy in this locality among the inexperienced. The time is coming when perienced. The time is coming when none but the progressive will keep bees—the sooner it comes the better. 1 am well pleased with the Weekly BEE JOURNAL. EDSON J. SMITH.

Addison, Vt., March 1, ISS1.

Good Enough.-With 12 colonies, in Good Enough.—With 12 colonies, in the spring of 1880, I increased to 35, by natural swarming, and obtained 1000 lbs. of surplus nearly all in 2 lb. sections, which I sold at 20 cts. per lb. at home. One colony gave off 3 swarms. My bees are all in good condition, and they will not need any feeding this spring.

E. DOTY.

Macksburg, Iowa,

Lost but few.-Our bees have had a fly, and we find we have lost but few but they are needing fair weather, and a backward spring would be disastrous. CHAS. DADANT & SON.

Hamilton, Ill., March 3, 1881.

About Half Dead.—I am well pleased with the Weekly Bee Journal. My bees are not wintering well. About one haif of each colony are dead now. It looks as though they would come out very feeble in the spring. M. S. North Wayne, Me., Mar. 1, 1881.

Packed in Chaff.—I have 153 colonies of bees packed in chaff.—All were alive at last examination about ten days ago, but they have not had a purifying flight with dysentery, a few badly. I fear a beavy loss unless the weather moderates soon. The American Bee Jour-NAL is very welcome as a weekly visitor.

Bangor, Mich. 11. D. BURRELL.

Good for a Novice.—I commenced last spring with 2 colonies partially Italian-ized, and increased, by dividing, to 8, 1 had a bee man look them over in the fall, who pronounced them in good condition and with plenty of honey. I ob-tained, also, about 20 lbs, of surplus. Is this not doing well for a novice, and a very poor season? Now, I want to try the prize box plan a little, can I use the comb honey rack and prize boxes on my hive? Is silver hull buckwheat valuable for grain and honey as other kinds, and would it pay to plant it sne cessively through the season for honey?

A. Hodges,

Shenandoah, Iowa, Jan. 26, 1881.

[The rack for the American hive, with a slight modification, will fit your hive nicely. Silver hull buckwheat is said to be superior to other kinds for all purposes; and where ground is cheap, we should think it would pay to plant it for a succession of bloom. You will find the other questions accompanying your letter frequently answered in previous numbers of the JOURNAL.—ED.]

Long Winter.—I doubted whether a Weekly BEE JOURNAL could be sustained; but now that it is under good headway, I am well pleased with it, and wish it sucess. I am sorry that, having increased my business more than ever, I cannot get time to write for it, as usual. I need not say that I never before saw such a winter as this. My bees, over 50 colonies, were all right January 30, except 4 of the weakest. They had then been confined about three months without a flight, though on their summer stands—a longer confinement than my bees ever had before. It is snowing and very cold now, and no telling how they will come out yet. the other apairy are all right, and if 1 do not lose over 10 colonies I intend to sell 30, as I shall not have much time to work with bees this year, but still I cannot do without the Journal. R. M. Argo.

Lowell, Ky., Feb. 28, 1881.

All the Natives Dead.—I commenced the winter with 35 colonies of bees and have only seven now, and they are my purest Italians. I have now 250 nice have only seven now, and they are my purest Italians. I have now 250 nice combs, each containing at least 4 lbs, of honey. I see that some advertise nu-clei—2 combs, 6x12, a small colony of bees—could they be built up to good colonies during the next season? I am better prepared for building up weak colonies than ever us all my neighbors? colonies than ever, as all my neighbors bees (100 colonies) are dead. I could have saved most of my bees had I known what the winter would be. I have got rid of my blacks, and have no idea of keeping them again. I now think the cause of my loss or gain, I do not know which, was zero weather in Nov., and for want of young bees, and, principally, corlessors, which follows a bad senson. I could give the condition of the bees that starved, but those that winter out of doors have only to open a hive and look! a little patch of brood and frost between them, etc. Wayeland, Ind. Peter James.

[Nuclei may be easily built up to good colonies, if they have prolific queens, by the aid of comb foundation.—Ep.1

Bees Need a Flight .- My bees have had a hard time for the last 3 weeks; from the 7th to the 10th inst, it was just warm enough to make them uneasy, but they could not fly without dropping to the snow and dying; for the 4 days above mentioned, the mercury stood from 30° to 35° above zero in day time : from the 10th to the 26th it was from 20

misty weather. Some of the colonies had a flight, but a good many dropped to the ground and died. My bees have not had a general flight since the latter not had a general fight since the fatter part of October. There was no day warm enough for it since. Four colo-nies out of 147, are dead, and quite a number are very weak; while in a great number of colonies, about 13 of the bees are dead, and if they do not get a flight soon, I expect about ½ of my colonies will die. They were in good condition, with plenty of stores, when winter set in; if they could have had a cleansing flight about Feb. 1st they madd the cleans of the colonies of the colonies. would have been all right.

C. Theilmann. Theilmann. Feb. 28, 1881.

Bees All Right.—My bees are all right. They had a nice "fly" on Feb-ruary 26th. Success to the Weekly Bee JOURNAL. S. S. Bristol. Galesburg, Mich., Feb. 28th, 1881.

Delighted with the Weekly.—I am delighted with the Weekly.—I had grown so attached to the old Monthly that I feared the change. But it was wise and timely; the added advantage from quick and frequent information will soon double the number of its subscri-bers. I had no idea of the force of this advantage till experience demonstrated it. To ask for information with assurance that it may come in a few days, is comforting and will surely be appreciated by all intelligent bee-keepers.
A. J. Cook.

Lansing, Mich., Feb. 21, 1881.

Rather Gloomy. —I had 10 colonies last fall and now have none; but this loss did not come unexpectedly. The colonies were very weak; there enough secretion of honey from about the 1st of June, to keep the bees alive; had they not had such a rich flow of honey early in the summer they would have died before the fall. I had thought of feeding, but that cold snap came on a little too soon, and killed all but 4 col-onies, and those were nearly gone, and died too. The clusters were too small, for all the colonies left some honey in their hives. I feel a little discour-aged, but am not despondent. I intend to purchase one or two colonies in the spring and take a new start. I will report of the neighborhood, 3 or 4 lost all, one 6 out of 7, another 5 out of S. you see that the season was a poor one.
H. Wilson Ulsh.

Middle Creek, Pa., Feb. 18, 1881.

Bee Moth, etc .- What is the best man-Bee Moth, etc.—What is the best manner of protecting surplus combs, for future use, against the ravages of the bee moth? Are the Cyprian and the Syrian bees, or either of them, superior to the Italian bee, according to the best authority upon the subject?
G. G. HUGHES.

Burlington, Ky., Feb. 9, 1881.

[For an exhaustive answer to the first question, see Mr. Doolittle's article entitled, "Bees Destroyed by Worms." It has not yet been demonstrated that, as a race, either the Cyprian or Syrian bees are superior to our American-Italians, though both may possess desirable traits which may be improved by judicious breeding or crossing.—Ed.]

An Excellent Crop.—My honey harvest for 1880 averaged, per hive, 30 lbs. of comb honey and 40 lbs of extracted. I left from 32 to 40 lbs. per hive, for winter. Thanks to the BEE JOURNAL. I have been able to get 70 lbs. of honey per hive, and double my stock in the poorest season that has been known in this part of the country; at the latter part of March the bees were gathering a good deal of honey from the maples. but with the month of April came cold, blustering weather; the month of May was also very cold. The sun shone about twice a week for half an hour or so, to tempt the bees from the hive; but half of those that went in qust of food never returned. June found the vice of the BEE JOURNAL, I kept them strong. My colonies are as strong or stronger to-day than they ever were, even at swarming time, before I got the

even at Sam....
BEE JOURNAL.
P. P. N. E. PELISSIER. Pelissier P. O., Ottawa Co., Que.

Stray Swarm.—On Nov. 13, father found a swarm of bees settling on an oak 250 yards from our apiary. I doubled them with a weak colony. It was a small swarm, and settled very naturally. There has been no honey gathered for at least 2 months, and will gathered for at least 2 months, and will will be a smany more. What made be none for as many more, them swarm? Chas. S. San Chas. S. Sanderson. Mt. Fairview, Cal., Dec. 17, 1881.

[It was a late swarm, which had been starved out.—ED.]

Enameled Cloth.—What is the enamel cloth, used for covering the brood chamber? Our stores contain nothing that seems reasonable to use for that purpose.

Nelson Hammond.
Traverse City, Mich., Feb. 19, 1881.

[Enameled cloth is cotton duck or sheeting enameled on one surface, and: usually sells at 25 to 30c. per yard.—ED.]

Cider a Cause Disaster.—There is a heavy loss of bees in Central Ohio, on account of impure honey gathered last fall. In some large apiaries all the bees are dead; but where the extractor was used last fall and the impure honey extracted, bees are wintering finely—none dving that have sufficient honey. number of bees died before mid-winter that had enough sealed honey to have carried them through the winter. Bees gathered a large amount of cider and impure honey-dew late in the fall, which they did not cap; it soon fermented and proved almost certain death to the I have no doubt but that a large share of the bees which are reported as dying of dysentery, might have been saved by the use of the extractor. I predict a good honey yield during the coming season. I love too well to hear the musical hum of their busy little wings to ever give up bee-keeping. AARON BENEDICT.
Bennington, O.

Colonies Strong and Healthy.—My bees had a splendid cleansing-flight on Feb. 25th. I have lost but one colony during this severe winter, and have some strongest colonies that I ever saw at this time of the year.

Joseph Elder. Huntington, Ind., March 2, 1881.

Will be Ready for the Harvest.into winter quarters with 40 colonies—38 were strong, and 2 were 3-frame nuclei; 25 were in the Root chaff hive, and the rest in Langstroth and simplicity hives. I prepared them for winter dur-ing the latter part of October, and from that time until the lst of February they had no flight. I found 36 colonies living. 1 queenless, and 2 that I could crowd onto 2 frames; all had sealed brood but 1, and I think they will all be ready for 1, and I think they was business in good time.
C. G. KNOWLES.

Portland, O., Feb. 28, 1881.

Ventilation. —I am glad the Weekly is established on a firm basis, for a weekly is indispensable to every progressive is indispensible to every progressive apairist. Our success depends upon close reading, instructive suggestions and thoroughly practical experience. My pets are wintering finely on their summer stands. Last summer, during the heated term, 2 combs in the center of the brood nest in one of my Italian colonies, melted and broke loose from the frames, consequently there was an indiscriminate mass, indicating imperfect ventilation. My hives are all protected from the moon-day sun. They fit close to the bottom board, with an entrance 8 inches wide, which some say is ample for ventilation. I have tried raising the hives and putting small blocks at the corners; this method adcolonies very much reduced, but brought mits the bee moth from all points of the from the 10th to the 26th it was from 20 us fine weather and an abundance of below to 20 above; on the 26th it was honey, so that the colonies became as high as 40 above, with calm, foggy, strong in a short time, and with the ad-

hive backward beyond the bottom board. This method is easier told than per-formed. For inconvenience, unwieldiformed. For inconvenience, unwieldiness and irritability, it is first class. I tried wire-cloth at the top of the chamber, only to find it enameled with prop-Bottom boards with holes cut in olis. Bottom boards with holes cut in and a ventilator slid under, make excellent receptacles for all the filth of the hive, if covered with wire-cloth. My experience is like Mr. Camm's—every mesh scaled. Please tell how to ventilate in hot weather? W. R. Young. Myersville, Md., Jan. 25, 1881.

[An entrance at the front and rear of the lave will furnish all the ventilation required, where the hives are shaded at noon-day, besides being a convenience to a strong colony during a plentiful honey flow. An inch hole in each end of the hive, about 2% up the brood chamber, covered inside with wire-cloth, will afford ample ventilation, and is plugged when no longer required.—ED.1

Alsike and Melilot.—My bees had their first flight on Feb. 24th. Since November 26th, 1880, we have had steady very cold-weather; the thermometer being once at 23° below zero. Bees in this location are all alive yet. I opened my hives yesterday; the bees are in very good condition, with plenty of brood, I had them in a shed packed with woolen blankets. I was glad to see the editor's likeness in the BEE JOURNAL. Which is the best for bee pasture, alsike or melilot clover? Peter Merlein.

Brussels, Il., Feb. 25, 1881.

Brussels, Ill., Feb. 25, 1881.

[Melilot is much the best.—Ep.1

Artifleial Pollen, etc.—1. On page 129, Vol. for 1880 of AMERICAN BEE JOUR-NAL, is an interesting article on the substitution of pea flour for pollen. Will it answer to use rye flour instead, mixing it in the same manner? and is

mixing it in the same manner; and it better stifted before using?

2. Last fall, while preparing my bees for winter. I put away several combs partly filled with unsealed honey from made of coffee A sugar. Will it syrup made of coffee A sugar. Will it do to feed this back in the spring, when the bees are flying freely?

3. What is the best method of giving

combs to the bees to have them cleane of loose honey? WM. STOLLEY. of loose honey? WM. STOLLE Grand Island, Neb., Jan. 14, ISSI.

[1. Unbolted rye flour will answer, and can be given in the same manner, though not so good. We prefer oatmeal, placed in tin pans at a short distance from the hives, and well protected from the wind.

2. If the honey is not soured, it can do no harm to feed back for early consumption, while bees are flying freely.

3. Place one frame each alternate day, or as fast as they are needed, in the brood chamber, using care not to chill the brood. A good extractor, however, will leave the combs dry and clean of honey, if not granulated.—ED.1

Spring Dwindling.—For the prevenspring Dynading.—For the prevention of spring dwindling my plan is, after setting them out and they have a good cleansing flight, to close the entrance entirely, so that no bees can pass; bore a 34-in hole 3 inches above pass; nore a 21-in noie 3 inches above the entrance and tack a wire-cloth over it; they will not smother when so treated. Leave them so until it is warm enough for them to fly. When cold evenings occur, close them up, and open when it is warm enough for safety, open when it is warm enough for safety, after the sun has warmed the air. This plan will also prevent the chilling of young larva, which are often dragged ont by the bees in the morning. Dead larva in the hive, is in my view, very conductive to foul brood, if not the main cause of it. Follow this plan until the weather is sufficiently warm to need no such care. Adopt the same plan in the such care. care. Adopt the same plan in the Bees here have not had a flight since going into winter quarters; those with plenty of stores seem to be all right as yet. Success to the Weekly BEE JOURNAL. J.B. IDE. Climax, Mich., Feb. 25, 1881.

# CONVENTION

#### Nebraska State Convention.

The Nebraska State Bee-keepers' association held its third annual meeting at Plattsmouth, February 10 and 11, and elected the following officers for 1881, viz: President, T. L. Von Dorn, Omaha; vice-president, S. L. Thomas, Plattsmouth; secretary, G. M. Hawley, Lincoln: treasurer, F. E. Caldwell, Balleyne

President Craig delivered the annual address before retiring from the chair, and W. C. B. Allen acted as secretary in behalf of Secretary W. G. Pigman, who was unable to be present.

who was unable to be present.

Papers were presented by Charles Dadant, of Hamilton, Ill., on "Spring Dwindling of Bees;" by G. M. Hawley, of Lincoln, on "Food Plants for Bees;" by T. L. Von Dorn, of Omaha, on "Drone Progeny" and "Bee-keeping for Profit;" and by T. S. Corhett, of Omaha, on "Bee Pasturage."

The meeting was the most practical and interesting ever held by the association, and a fair attendance was had

and interesting ever held by the asso-ciation, and a fair attendance was had from Washington, Douglas, Sarpy, Cass and Lancaster counties. Mr. James T. Fife, president of the South-western Iowa Bee-keepers' association, from Corning, Iowa, was invited to take part in the proceedings. A two days' dis-cussion ensued upon various topics of bee-culture, including "Wintering Bees," "Increase of Colonies," "Bee bee-culture, including "Wintering Bees," "Increase of Colonies," "Bee Pasturage," "Marketing Honey," "Comb, or Extracted Honey," and the practical experience of the members called out by questions and answers.

Besolutions of respect were passed to

Pasturage, "Comb, or Extracted Honey, practical experience of the members called out by questions and answers.

Resolutions of respect were passed to the memory of Dr. II. Munger, of Omaha; also resolutions of thanks to the people of Plattsmouth, and to the railroad companies for reduced rates and other courtesies.

G. M. Hawley, J. J. McLain and T. S. Corbett were appointed a committee to take charge of the exhibit of the bee-keepers at the next State Fair.

"The order to have this Table complete, Secreta
"The order to have this Table complete, Secreta-

nection with apiculture, is one that is fraught with much interest, and if I fraught with much interest, and if I can say anything that will cause horticulturists of my own State to investigate and test the two pursuits together, I shall feel amply rewarded for my effort in that direction. I am aware that there is a prejudice against fruit-raisers keeping bees; but I regard the bees necessary to success in horticulture. In fact I regard aniculture as the handfact, I regard apiculture as the hand-maid of fruit-culture.

The office that bees perform in the fertilization of the flowers of most all

fertilization of the flowers of most all our fruits is of primary importance, and cannot be dispensed with without loss. I am aware that many other insects perform the same office to a limited extent; but the honey bees, much more than all, carry the pollen from flower to flower, and by that means the flowers are fructified, and in return furnish the bee with both bread and honey—its natural food. Thus yon see the importance of combining fruit and honey—its natural food. Thus you see the importance of combining fruit and bee-culture. Where there are no bees, flowers fail to set their fruit to a great extent, and the consequence is a short crop. If you have bees sufficient to gather the rich stores from your gar-dens and orchards, you will thus secure the most wholesome and delicious food for you tables the world affords; food fit for you tables the world affords; food fit for the gods—pure, unadulterated honey. unlike the vile stuff we often buy from the grocery, mixed with glucose made

lention, and have never seen bees punclention, and have never seen bees painc-ture or tear open perfectly sound grapes; not that they could not, but that they will not. Birds, wasps and hornets are destructive to grapes, and when they are punctured the bees follow and take up the wasted sweets; and, being so much more numerous, are noticed by the observer, while the real depredators the observer, while the real depredators

If you will take a bunch or so of ripe, If you will take a bunch or so of ripe, sweet grapes and puncture half of them, and put them near a hive of bees, you will see that the bees, after taking up the sweets from the punctured grapes, will leave the ones that are sound and perfect. In wet weather, when sunshine and showers alternate, grapes will crack open and bees will collect in leaves authorise that are large numbers on them, and all that are imperfect will be rifled of their sweets, and the bees are condemned for the destruction, when, in fact, they are not guilty. In France and Germany, where wine is extensively made, bees are kept in large numbers; and also in California. Then I would say to all who are engaged in fruit-raising, keep bees; at least sufficient to supply your tables with honey, if not to fill your pockets with money. with money.

Bee-keeping is both pleasant and profitable. It is elevating in its tendency, as it brings us in close contact with nature, and through nature we look up to nature's God; and thus we are made better by observing the won-tens working of the tiny her working. drous working of the tiny bee in constructing its waxen cells, rearing its young and gathering the fragrant sweets from nature's flora.

"Garden and orchard-lawn, and flowery mead;
The blue-veined violet, rich columbine,
The wanton cowslip, daises in their prime,
With all the choicest blossoms of the lea,
Are free allowed and given."

ries are requested to forward full particulars of time and place of future meetings.—ED.

### Honey and Beeswax Market.

BUYERS' QUOTATIONS.

### CHICAGO.

CHICAGO.

HONEY-The market is plontifully supplied with boney, and sales are slow at weak, easy prices. Quotable at 18@20c. for strictly choice white comb in 1 and 21b. boxes; at 14e.05c. for fair to good in large pickages, and at 19@12c. for common dark-colored and broken lots.—Chicago Times.

BEESWAX.—Choice yellow, 20@24c; dark, 15@17.

### NEW YORK.

HONEY.—Best white comb honey, small neat packages, 17@18c; fair do., 15@16c; dark do., 12@15; large boxes sell for about 2c under above. White extracted, 9@10c.; dark, 7@8c.; southern strained,

BEESWAX.-Prime quality, 20@25c.

## CINCINNATI.

HONEY.—'The market for extracted clover honey very good, and in demand at 11c. for the best, and 28c. for baswood and dark honey. Comb honey so fislow sale at 16c. for the best.

What is the meaning of 'Dec. 81' after my name on the direction-label of my paper?" This question

## SPECIAL NOTICES.

 $\hfill \ensuremath{\mathbb{Z}}$  When changing a postoffice address, mention the old address as well as the new one.

₩ We have prepared Ribbon Badges for bee-keepers, on which are printed a large bee in gold. Price 10 cents each, or \$8.00 per hundred.

The Volume of the BEE JOURNAL for 1880, bound in stiff paper covers, will be sent by mail, for \$1.50.

TO Notices and advertisements intended for the Weekly BEE JOURNAL must reach this office by Friday of the week previous.

Instead of sending silver money in letters, procure t, 2 or 3 cent stamps. We can use them, and it is safer to send such than silver.

The date following the name on The date following the name on the wrapper label of this paper indicates the time to which you have paid. In making remittances, always send by postal order, registered letter, or by draft on Chicago or New York. Drafts on other cities, and local checks, are not taken by the banks in this city except at a discount of 25c to now expense of at a discount of 25c., to pay expense of collecting them.

Premiums.—For a club of 2, weekly, PREMIUMS.—For a club of 2, weekly we will give a copy of "Bee-Culture;" for a club of 5, weekly, we will give a copy of "Cook's Manual," bound in cloth; for a club of 6, we give a copy of the JOURNAL for a year free. Do not forget that it will pay to devote a few hours to the BEE JOURNAL.

Sample copies of the Weekly BEE JOURNAL will be sent free to any names that may be sent in. Any one intending to get up a club can have sample copies sent to the persons they desire to interview, by sending the names to this office.

Any one desiring to get a copy of the Constitution and By-Laws of the National Society, can do so by sending a stamp to this office to pay postage. If they desire to become members, a fee of \$1.00 should accompany it, and the name will be duly recorded. This noname will be duly recorded. This notice is given at the request of the Exec-

11 would save us much trouble, if all would save us much trouble, if all would be particular to give their P.O. address and name, when writing to this office. We have several letters (some inclosing money) that have no name. Many others having no Postoffice, County or State. Also, if you live near one postoffice and get your mail at another, be sure to give the address we have on our list. dress we have on our list.

At the Chicago meeting of the National Society we were requested to get photographs of the leading apiarists, to sell to those who wanted them. We can now supply the following at 25 cents each: Dzierzon, the Baron of Berlepsch, and Langstroth. The likeness of Mr. Langstroth we have copied, is one furnished by his dayafter, who says of Ar. Langstoth we have copied, is one furnished by his daughter, who says, "it is the only one ever taken when he was in good health and spirits." We are glad to be able to secure one of such a satisfactory nature.

We have filled orders for quite a number of Binders for the Weekly Bee for you tables the world affords; food fit for the gods—pure, unadulterated honey. In the grocery, mixed with glucose made from corn and potatoes.

Bees kept on the improved plan are very profitable—often paying from 100 but some of our wine-growers will tell you they are destructive to vineyards, and that you cannot keep bees and grapes together for a number of years, and have given them my personal at-

## Books for Bee-Keepers.

Cook's Manual of the Apinry.—Entirely rewritten, greatly enlarged and elegantly illustrated, and is fully up with the times on every conceivable subject that interests the apinrst. It is not only in structive, but intensely interesting and thoroughly practical. The book is a masterly production, and one that no bee-keeper, however finited his means, can afford to do without Cloth, \$1.25; paper covers, \$1.00, postpand. Per dozen, by express, cloth, \$12, paper, \$9.30.

quinty's New Bee-Keeping, by L.C. Root.— The author has treated the subject of Lee keeping in a manner that cannot tall to interest all. Its style is plant and forcible, making all its readers sensible of the fact that the author is really the master of the subject. Price, \$1.50.

Novice's A B f of Bee-Culture, by A. I. Root. This embraces "everything pertaining to the eare of the honey-ties," and is valuable to beginners and those moreadvanced. Cloth. \$1.25; paper, \$1.06.

King's Bee-Keepers' Text-Book, by A. J King. This edition is revised and brought down to the present time. Cloth, \$1.00; paper, 75c.

Langstroth on the Hive and Honey Hee This is a standard scientific work. Price, \$2.00,

Blessed Bees, by John Allen.—A romance of bee-keeping full of practical information and con-tagious enthusiasm. Cloth, \$1.00.

agious enthusiasm. Cloth, \$1.00.

Recellulture; or Successful Management of the Apinry, by Thomas G. Newman. This pampillet embraces the tollowing subject to the control of the Apinry Honey Plants-break Honey Rapinry Honey Plants-break Honey Swarming - Daviding - Transferring-Lucianizing Introducing Queens Extracting-Quieting and Handling Rees The Newest Method of Preparing Honey for Market, etc. It is published in English and German. Price for either edition, 40 cents, postpaid, or \$3.00 per dozen.

Food Adulteration; What we get and should not eat. This book should be in every family, where it ought to create a sentiment against the adulteration of food products, and demand a law to protect consumers against the many health-destroying adulterations offered as food. 200 pages. Paper, 50c.

The Dzierzon Theory; presents the fundamental principles of ber-culture, and furnishes a condensed statement of the facts and arguments by which they are demonstrated. Price, 15 cents.

which they are demonstrated. Price, 15 cents.

Honey, as Food and Medicine, by Thomas G.
Newman.—This is a pamphlet of 21 pages, discoursing
upon the Arcient History of Bees and Honey; the
transparent of Honey of Honey of Honey
or the Market; Honey as an article of Honey
or the Market; Honey as an article of Honey
from Wines, Acc; and Honey as Medicine, followed
by many useful Recipes. It is intended for consumers, and should be scattered by thousands all over
the country, and thus assist in creating a demand for
honey. Published in English and German. Price
for either edition, Gc; per dozen, 50c.

Wintering Bees.—This pamphlet contains all the Prize Essays on this important subject that were read before the Centennial Bee-Keepers' Associa-tion. The Prize-\$2 in gold—was awarded to Prot. Cook's Essay, which is given in full. Price, 10c.

Hees and their Manngement. This pamphlet was issued by the Italian Bee Company, and has had a large circulation. The price has been reduced from 20 cents to 10 cents.

The Hive I Use—Being a description of the hive used by G. M. Doolittle. Price, 5c.

Kendall's Horse Book - No book can be more useful to borse owners. It has 35 engravings, illustrating positions of sock hoses, and trents all diseases in a plain and comprehensive manner. It has a large number of good recipes, a table of doses, and much other valuable horse information. Paper, 25c.

Chicken Cholera, hy A. J. Hill,—A treatise on its cause, symptoms and cure. Price, 25c.

Moore's Universal Assistant contains information on every conceivable subject, as well as receipts for almost everything that could be desired. We doubt if any one could be induced to do without it, after having spent a few hours in looking it through. It contains 430 pages, and 500 engravings. Cloth, #2.50.

Ropp's Easy Calculator.—These are han tables for all kinds of merchandise and interest, is really a lightning calculator, micely bound, w slate and pocket for papers. In cloth, \$1.00; X rocco, \$1.50. Cheap cillion, without slate, 50c

## Pure Liquid Honey in Glass Jars.

CHAS. DADANT.

Under this heading I find an article from Mr. W. M. Hoge, who says that he has invented a way of preparing liquid honey so that it will not congeal. He adds that this discovery will be beneficial to bee-keepers, and he explains how we will profit by it. The tendency of honey to candy, for all the adulterators of honey, has proved to be a great impediment; while, for the producers, it is a good characteristic, for it is the best stamp that a bee-keeper can put on his product—a stamp that the adulterahis product—a stamp that the adultera-tors are unable to counterfeit.

Now that the consumers at large begin to give their preference to candied honey, the adulterators, seeing their sales decreasing, try to invent some means to stop this result, and incite us to help them to continue their fraudulant practice.

lent practice.

Let us remember that the candying Let us remember that the candying of honey is the best test of purity thus far; that, by preventing honey from candying, we lower it to the level of glucosed honey; and that, as long as liquid honey can be found on our markets, we will be compelled to compete with adulterated honey, for the profit of this adulteration will always tempt the inscriptions dealers while we will be unscrupulous dealers, while we will be unable to compete with them for the

cose. These jars and tumblers are now of slow sale, for the consumers begin to of slow sale, for the consumers begin to have confidence in candied honey. We are, therefore, in a fair way for selling our product. Let us go on, and turn the cold shoulder to the advice of those who have, so far, caused more prejudice than profit to bee-keepers.

Mr. Hoge, who has visited the old continent, knows, as well as I do, that in Europe liquid honey is unsalable, for the consumers are accustomed to buying candied honey. Let us persist in

ing candied honey. Let us persist in our efforts to educate the people on this question, and we will drive all spurious honey from our markets. Hamilton, Ill., Feb. 2, 1881.

For the American Bee Journal.

## Colchian Honey.

REV. W. BALLENTINE, A. M.

I see in the BEE JOURNAL, under the above caption, a question from Mr. H. G. Colwell, of Columbus, Ohio, relative to the effects of honey eaten by the Grecian troops, under Xenophon, as they passed through Colchia in their fathey passed through Colchia in their famous retreat homeward. In regard to this, you propose a query, "Why did the ancient Colchian honey cause the above disorder?" I have frequently had my attention turned to this subject in reading Xenophon's Anabasis in the original, from which the extract by Mr. Colwell is taken. From the best sources of information at my command, the following seems to be the most rational.

tional.
The honey of Asia Minor in many lo-The honey of Asia Minor in many localities appears to be gathered from the flowers of the order Apochynoceae, or dog-bones. Of this order, Prof. Wilson, in his botany, page 588, observes: "These plants possess active, and often suspicious qualities, residing in the white juice with which the order is pervaded, and in the seeds, which are often deadly poisons. The alkaloid astychine, or strychinea, one of the most violent poisons, is the active principle of the Strychorea Nux-vomica, of India. It is sometimes administered as a mediis sometimes administered as a medicine, but with doubtful success; a single seed of one species is sufficient to kill 20 persons. The order is generally amoutia.

In corroboration of this, I will give you the opinion of the celebrated Ainsworth, who traveled over the route of the Grecians, and took notes of all the localities and incidents recorded by Xenophon. He observes that this fact of the honey of Asia Minor being, in certain places, and at certain seasons, of a poisoner pattern was known to all a poisonous nature, was known to all antiquity, and is very common at the present day, so much so, that I have known the peasants to inquire if we would prefer the bitter or the sweet honey, for the honey so qualified has a slight but not upplessent bitterness. unable to compete with them for the price.

A few years ago we could find liquid honey, in glass Jars, in every good grocery. Three years ago I produced, at the Western Illinois and Eastern Iowa Convention, held at Burlington, Iowa, one of these bottles, bought in St. Louis, labeled "Pure Extracted Honey, from John Long, New York." Mr. Hoge, who resided in New York at that time, probably knows "John Long." This "pure honey" was analyzed by an expert chemist and found mostly glu-

Heroclea Pontica. The celebrated botanist, Tournefoil, ascertained on the botanist, Tournefoil, ascertained on the spot, that the honey of bees feeding on the Azalea Pontica, as also on the Rhododendrom Ponticum, possessed mischevous properties; but as the bitter and intoxicating honey is found in many parts of Asia Minor, where these plants do not flower, it is extremely probable that these peculiar properties are further derived from the flower of the Neriun Oleander, or common rose-laurel, the leaves of which are known to be acrid and poisonous. The natural family to which the rose-laurel belongs (apocyhnaceæ)is distinguished by plants endued with dangerous and fatal properties, and these act on the nerves so as to produce stupefaction. Rhodaraceæ also possesses narctoic properties, as to produce stupefaction. Rhodaracee also possesses narctoic properties, but in a less marked degree."

It appears from this, that the honey

It appears from this, that the honey gathered by the bees from these poisonous plants, possessed some of the inherent qualities of the plants themselves, and operated like a narcotic or opiate on the nerves, producing stupefaction and intoxication. If you see proper you can give the above a place in the Weekly, with which I am, so far, very well pleased.

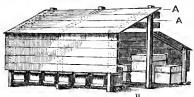

Sago, Ohio.

For the American Bee Journal. Combined Summer and Winter Stand.

II. L. PENFIELD.

The engraving shows a perspective view of a combined winter and summer stand, which I put up to accommodate 12 hives of the standard Langstroth 12 hives of Put in the ground 9 oak posts 4x4 inches, for a frame to nail the 14 foot boards to

3 posts on each side, and 3 between these set in the ground 10 inches. these, set in the ground 18 inches. The

A. A—Ventilation and bee escape. B—Space to work in and shaded.

ends are 9 feet wide, which I find gives ends are 9 feet wide, which I find gives ample room to manipulate the bees between the rows of hives, the operator being in the shade, and not in front of the entrance of the bees, which seldom bother me. The sides front east and west. The ends are open during the summer, and the north end boarded up in winter. We use millet hay for protection, filling in spaces between the hives, and over and under them, almost filling up between the rows, clearing away enough in front of the entrance for the bees to take a flight when the weather permits. weather permits.

weather permits.

This protection keeps them quiet, and storms beat on the shelter and on the millet hay. Of course, this is not a water-proof shelter or cover, and I do not think one is needed. It is advantageous to have an opening in the apex of the roof; this plan of having one roof higher than the other secures it with the least expense. It is curious to

notice how the bees fly out of these spaces marked A, A (as both ends are spaces marked A, A (as both ends are open) while the operator, is manipulating the hives. Sixteen boards 14 feet long and 1 foot wide cover it, and with the 9 posts and 4 2x4 studding to set the hives on, and short pieces to set on top of the posts to nail the roof to, complete the lumber bill.

Hunnewell, Mo.

For the American Bee Journal.

#### Foul Brood, and Its Causes.

H. L. JEFFREY.

You ask for my observations on foul brood regarding the cases noted in the BEE JOURNAL. There are many who, I know, will disagree with me, but nevertheless, it seemed to come from no other source. The largest case of it was other source. The largest case of it was 25 colonies in one apiary. Ever since the year 1873 they had been wintered in the cellar, in a sort of room fitted up especially for them. They were usually put in about Nov. 25, and taken out about April 1st to the 20th, according to the season. This receptacle was directly under the living room, which was kept very warm. The bee-room was generally quite dry, and towards spring would stand from 45° to 50°, which would let the bees have from 60° to 80° in the hive, or perhaps 90°, causing the cluster to spread, and there was always a good supply of brood in the combs when taken from the cellar, and generally a consid-

supply of brood in the combs when taken from the cellar, and generally a considerable number of young hatched bees. So far everything was as good as could be asked for, and every good bee-keeper will say this could not have anything to do with foul brood; perhaps not.

These same hives, with more space and more surface of comb than a 10 frame Langstroth hive gives, were put into the cellar with all their combs in place, with a box 6 inches deep below the hive, and another above filled with straw, or with a top story filled with rags, old clothes and pieces of carpet or straw. The full complement of combs rags, old clothes and pieces of carpet or straw. The full complement of combs was left in the hives, regardless of the strength of the colonies, and they were then set on their summer stands without using division boards, or any contraction of combs. After setting out they were generally fed liberally every night to induce breeding, which is a good plan if properly handled, but in this case it helped to breed the disease, and it did do it to the fullest extent. Why? First, a small colony should not be given any more combs than it can cover, either in summer or winter. If the hive is too large, insert a division on the hive is too large, insert a division on one or both sides; if on both sides, let one of them be at least half an inch shallower than the hive, then if the numbers increase, they can crowd outside of it.

of it.
Second, if they are wintered in-doors, in a hive full of combs, take away all you can before they are set out in the spring, even if you have to feed to prevent starvation.
Third, if you do winter in-doors on a full set of combs, do not commence feeding regularly, to induce breeding, as soon as set out, though it be the 25th of April or even the 1st of May.
In the case mentioned the consequences were: In the weak colonies some of the bees died in the combs and

contracted some moisture, consequently would mold. Some strong colonies would do the same, but many of the dead bees would be thrown down. The dead bees would be thrown down. The cellar had a drain 100 feet long, with a fall of 5 feet, to keep the cellar dry, and a ventilator 3 feet above the house-sill outside, at the south. The ventilator opened on warm days, consequently a draft of warm air, fire in the room above, temperature in the bee-cellar raised, cluster of bees spread, queen goes to laying, honey consumed, brood reared and old bees wearing out; all of these conditions are the requisites of these conditions are the requisites of good, strong, healthy colonies, and they are just as surely the forerunners of tirst-class cases of foul brood every time.

I know that 99 out of every 100 bee-keepers will differ with me, but go through the colonies with me 10 or 15 days after setting out on the summer stands; suppose in that time we have had 2 or 3 good flying days; the feeding induced the queen to lay more rapidly and forced the cluster to spread; the eggs hatched into larvæ; on the pleasdays the old bees flew out but forgot to fly in again, thus diminishing the cluster; then there came 2 or 3 stormy days in succession, cold and chilling; cluster contracted as well as diminished in numbers; the minute larvæ starved and dead, and some, perhaps, that are advanced to capping; another flying day, and their numbers are more reduced. The dead bees in the combs putrefy, and you have for your pains a first-class case of foul brood in the near future. Many will shake their heads, but I saw the colonies, and in 3 years I saw the 25 and their increase decreased to 17, the 17 and their increase decreased to 9, the 9 down to 2, and the 2 went, in the spring of 1880, "where the woodbine twineth."

## Early Importations of Italian Bees.

REV. L. L. LANGSTROTH.

I can probably give, better than any one living, the history of the first efforts one living, the history of the first efforts made to introduce Italian bees into this country; as I knew well the late Messrs. Samuel Wagner and Richard Colvin, and Messrs. S. B. Parsons and P. G. Mahan, who, with myself, were the first to import them. Messrs. Wagner and Edward Jessop, both residents of York, Penn., received from Dzierzon, in 1856 a colony of Italian bees which in 1856, a colony of Italian bees which had starved on ship-board. Mr. Waghad starved on ship-board. Mr. Wag-ner's letter to me, August, 1856, and given the next spring, in my 2nd edi-tion on bees, is the earliest notice, pub-lished in this country, of the Italian race of bees. Messis. Wagner and Colvin, subsequently, bought a few queens of Dzierzon, which were con-signed to the care of the surgeon of a Bremen steamship, who had been care. Bremen steamship, who had been carefully taught what precautions to use for their safety. Fearing that the bees might sting his passengers, the captain would not allow them to be put on his

In the winter of 1858-59," (I quote "In the winter of 1858-59," (I quote from Mr. Colvin's able article on beekings, in the Report of the Commissioner of Agriculture for 1863, page 530.) "another attempt was made by Mr. Wagner, Rev. L. L. Langstroth, and myself. The order was placed in the hands of the surgeon of the steamer, to whose charge the bees were to have to whose charge the bees were to have been committed, but in consequence of been committed, but in consequence of his determining to leave the ship, the effort failed.\* Subsequently arrangements were made, in the latter part of that year, and we received 7 living queens. Only two or three young queens were reared by us during that fall and winter, and in the following spring we found that all our imported stock had perished. In conjunction with Mr. Wagner, I determined to make another perished. In conjunction with Mr. Wagner, I determined to make another

\*Mr. Colvin, having formed the acquaintance of the German Captain, not only convinced him that the bees could not escape to injure any one, but inspired him with a strong desire to be the first to bring over in his own vessel, this valuable race of bees. It would require quite a volume to tell, at length, what sacrifices of time were made by Messrs. Wagner and Colvin, to secure these bees.

rive until June, 1860."

Our queens, which came in 1859, were in charge of a German resident of Brooklyn, N. Y., who was returning home from a visit to his friends, and to whom Mr. Wagner had given very careful directions how to care for them. This person, learning that Mr. Mahan had expressed the intention of having the hoper of landing in America, the the honor of landing. in America, the first living Italian bees, and desiring, as he told me, to secure this honor for us, communicated Mr. Mahan's intention to the captain, who, as soon as the gang-way was in place, was the first person to step ashore, proclaiming with a very loud voice: "These are the first Italian bees ever landed on the shores of America!"

In the spring of 1856, Mr. S. B. Parsons, of Flushing, L. I., invited me to visit him, and advise with him as to the best way of managing his Italian bees. On my way, I called upon Mr. Mahan, who was joint owner with me of a large integer in my parton him. of a large interest in my patent hive. He gave me a very graphic account of his visit to the apiary of the Baron Von Berlepsch, from whom he obtained a queen, and supplied me with a few Italian workers for Prof. Joseph Lidy, that he might determine how the length of proboscis, in that variety, compared with that of the black bee. On arriving at Flushing, Mr. Parsons showed me tive hollow logs, or "gums," placed in an old bee-shed. It was a warm, sunshing day, and I am only a programme in the state of shiny day, and I saw only an occasional bee flying out from one of the hives. These colonies had been purchased in Italy, carried safely on the backs of mules over the Alpine passes, to Genou, from which port they were safely shipped to New York; but by a succession of mishaps, four of them died at Flushing. The fifth contained a mere handful of bees, with their queen, which I introduced to a colony of black bees. It is hardly necessary to say that none of these hives were ever in the same vessel with Mr. Mahan.

On the 18th of April, the steamer Argo arrived in New York, after a tedious and stormy voyage. Mr. Herman, a German bee-keeper, and author of a work on the Italian bee, who had been work on the Italian bee, who had been furnished with a large sum of money by Mr. Parsons to buy Italian bees in the best districts of Italy, and who had agreed to bring them over in the original hives, and breed queens for Mr. Parsons, was not on board, but in his place, a young Austrian, by the name of Bodmer. On the 19th, as soon as the bees were allowed to be landed, they were carried to Flushing. The small were carried to Flushing. The small boxes in which they were put up were in three different packages, one of which was consigned to the U.S. Govwhich was consigned to the C. S. Gov-ernment, one to Mr. Mahan, and one to Mr. Parsons. As the Austrian said that he knew, by examination on ship-board, that the bees were in a very bad condition, and many of them already dead, and, as the day was very pleasant, they were all examined under my personal supervision, and I can assure Mr. sonal supervision, and I can assure Mr. Robinson that every colony consigned to the Government and Mr. Mahan, was dead. A few, only, of those marked for Mr. Parsons, had living queens, some of which soon died, and in a short time he found himself the possessor of only two queens, one of which was the queen found alive upon my arrival at Elushing.

Flushing.

By my advice, Mr. Wm. W. Cary, of Coleraine, Mass., a very skillful beekeeper, and a thoroughly trustworthy man, was sent for by Mr. Parsons. One of the queens was entrusted to his care, on the premises of Mr. Parsons, and the other to Mr. Bodmer, some distance off, who did not raise queens enough even to pay for the black bees and honey which were purchased for his use; while Mr. Cary Italianized a large apiary for Mr. Parsons, besides filling all his or-

trial; the queens, however, did not arrive until June, 1860." which they were prepared by Mr. Cary and himself, for so long a voyage. The Dur queens, which came in 1859, were bees sent to Mr. Parsons were in cigar boxes. into which the combs were boxes. Into which the combs were merely crowded or wedged: the loosen-ing of the combs on so rough a voyage killed some of the queens, while others were drowned, with their bees, in honey: were drowned, with their bees, in heard, and others, still, starved from the boxes being over-crowded with bees. It is hardly necessary to contrast Mr. Bighardly necessary to contrast Mr. Big-low's success with the heavy losses suslow's success with the heavy tosses sustained for years by those who imported bees from Europe. The result of Mr. Parsons' dealings with Herman were, that for \$1,200 advanced to him, he had only 2 queens to show. The next season Mr. Bodmer, having learned how to over a number of queens in good condition, for Mr. E. W. Rose, but was very unfortunate in the management of them. Herman came, some years after, to the country and was employed by to this country, and was employed by a friend of mine in Philadelphia, to pur-chase for him, in Italy, a large number of queens. The return voyage was long and stormy, and every queen died on board the steamer. Oxford, Ohio, March 5, 1881.

## A Good Way to Promote Bee-Keeping.

WM. F. CLARKE.

As a sample of what may be done in many parts of the country to diffuse knowledge regarding apiculture, and awaken an interest in bee-keeping as a business, let me give a brief account of a meeting recently held in Shaftesbury Hall, Toronto, under the auspices of the Y. M. C. A. Mr. D.A. Jones, having made the acquaintance of some of the leading spirits in the organization just named, offered to give a free lecture on bee-keeping. The offer was accepted, and a meeting announced to which the members of the Y. M. C. A. were admitted gratis, while the general public were charged a small fee. Mr. Jones were charged a small fee. Mr. Jones invited the writer to be present as a reserve force, in case he should break down, (!) and what enthusiastic beekeeper would not rally to the rescue when thus appealed to? Unfortunately Mr. J. was not in good trim, having been sick enough to keep his bed most of the day preceding the lecture evening. However, he gathered himself up for the task he had undertaken, and was cheered by the appearance of his ally just as the lecture was about to begin. For a sick man, he did bravely. For a sick man, he did bravely gm. For a sick man, he did bravely, and spoke for nearly an hour. His remarks were, of course, general, and very different from what they would have been if his audience had been composed of experienced apiarists. He discoursed on bee-keeping as a business, explained the outlines of it, showed that it was profitable, and especially dwelt upon the gain which would accrue to the country if it was programmally to the country if it were more generally engaged in. An interesting sketch of his journey to Cyprus and the Holy Land formed the latter part of his address. The writer supplemented his remarks by a talk of about half an hour, the chief theme of which was advice to the chief theme of which was advice to intending bee-keepers. There was a far larger audience than might have far larger audience than might have been expected, considering the preva-lent apathy in regard to apicultural pur-suits, and considering also that the weather was unpleasantly stormy. Much interest was evidently awakened; a number of questions were asked at the clear of the addresses, and many the close of the addresses, and many lingered when "meetin" was out "to talk about bee-matters. An immense amount of good might be done if practical bee-keepers would engage in this kind of missionary work. The public is a dull scholar, and needs to be "enthused" by men who have the true apieultural spirit. Among other questions, these were asked:—" What is the best these were asked:—" What is the best bee journal?" and "What is the best book on bee-keeping?" The AMERI-

Jones' meeting the credit for having inspired them. There are not only Y. M. C. As., but other organizations all over the land that would be glad to have a meeting in the interests of bee-keeping. If 2 or 3 practical bee-keepers would divide the work and responsibility of maintaining such a meeting it. ity of maintaining such a meeting, it would not be so formidable, as though only one man undertook it. A plain, common-sense talk on a subject of such practical and commercial importance as bee-keeping, would be a welcome change from the elaborate lectures usually de-livered before Y. M. C. As., Lyceums, and bodies of that ilk. I hope Jones' enthusiastic zeal will stir others up to emulation and imitation. Reader, if conscious of possessing "the gift of the gab" in any degree, "go thou and

## Do Bees Injure Fruit?

F. P. BOUTEILLER.

A prominent wine-grower in this country, told me, about a year ago, that he did not want bees in his neighbor-hood as he found they injured his grape crop. As I have a small grapery, of about a hundred plants, between the rows of which I find shelter for about 20 colonies of bees. I determined to ob-20 colonies of bees. I determined to observe if his theory was correct, for I was loth to give up either. If any fruit crop could be injured by the visit of bees, mine is surely the one. The result of one season's close observation has convinced me: 1st. That bees promote rather than injure the foundations of fruit buds, because the bunches on my vines were full, with better developed there is then those produced on veloped berries, than those produced on vines less exposed to their visits, and my peach and cherry trees were as fairly loaded with fruit as they well could be. 2nd. That in the fall bees only visit our ripe berries, that have been sweetened by early frosts, and are very ripely seen on a god sound fruit. been sweetened by early frosts, and are very rarely seen on good sound fruit, when the skin is unbroken, and that the loss from this cause is of very little consequence, as the fruitattacked would fall off itself, without the visit of the bees, before gathering. I am wintering 21 colonies, mostly Italians; procured one of Jones' Cyprian queens, but too late in the fall to speak intelligently of the result. They are on summer stands, well sheltered and surrounded with straw, having means of exit, and with straw, having means of exit, and I think are wintering well, but they have not had a good fly since early in November

Belle River, Ont., March 5, 1881.

### Remarkable Tardiness in Fecundity.

G. W. DEMAREE.

One of my Cyprian queens has upset an established doctrine in bee-science, set at naught all the bee-books, and reversed the old adage which says: "hope long deferred maketh the heart sick." In the latter part of last season I reared some Cyprian queens from eggs and larvæ, obtained from Mr. Root; they were 7 in number, and were hatched on were 7 in immort, and were natched on the 6th, 7th, and 8th days of Sept. The weather being warm and fair they were all fertilized (except one, which never returned from her bridal tour) by the 12th of the month, and a few days later they were all laying except one; that being the finest, brightest-looking queen being the finest, brightest-looking queen of the lot, stubbornly refused to commense the duties of a good queen. She was in a strong nucleus which was fed regularly and bountifully, till the hive looked as though the occupants were enjoying a bountiful white clover harvest, but "nary an egg would she lay." She was provided with a clean empty good by leading the center of the color.

One hundred and eleven queens were carried to California, by Mr. A. J. Biglow, 108 of which reached there in good and, "What is the best book on bee-keeping?" The American Cook's "Manlow, 108 of which reached there in good and, and Cook's "Manlow, 108 of which reached there in good and," were the replies given. In his counsels to beginners, the writer insisted very strongly, that the first step in practical bee-keeping was to get a good hand-book, and journal of apiculture. So, if you receive orders from Toronto for the American Bee Journal of the long siege of snow and bitter winds which lasted till the 30th of Jan.; on that date our bees enjoyed a good,

cleansing flight, and I remembered my cleansing flight, and I remembered my non-laying queen and proceeded to look her combs over, and to my surprise, on one of the center combs I found a little patch of brood about half as large as a postal card, some of which was sealed over. It was genuine worker brood, and no mistake. Since which time she has been laying nicely, and now has a nice lot of brood for the time of year.

My bees, 30 colonies with selected

nas been raying nicety, and now has a nice lot of brood for the time of year.

My bees, 30 colonies with selected queens, have come safely through the winter to the 1st of March, and there is really but little danger of losing bees in this climate after the 1st of this month, unless they are short of stores and shamefully neglected. The beeman is aware, above all others, that there is "many a slip betwixt the cup and the lip," however closely he may watch his business. On the 30th of Janlast, when my bees were flying lively, I noticed that one large colony with a tested Cyprian queen, were not stiring like the others. I proceeded to open the hive and found the bees so nearly starved that they could only show signs of life by a feeble motion of their wings, which produced no sound whatever. which produced no sound whatever. Not a bee seemed able to change its po-Not a bee seemed able to change its position; the fore-runner of death was already present in the form of a cold, damp atmosphere in the brood chamber. I prepared some rich sweetened water, separated the frames gently, and sprinkled the bees thoroughly with the sweetened water, and poured some of it into the empty cells. The frames were then readjusted and a dry woolen quilt spread over the bees and the sun permitted to shine into the hive. In about spread over the bees and the sun permitted to shine into the hive. In about an hour I raised the quilt and the inmates of the hive were stiring briskly. handing around the good cheer, while some of them showed fight in a most patriotic style. They were provided with stores, and are now a No. I colony. So much for bee-science. What a lesson this teaches? Here was

What alesson this teaches? Here was a large colony of bees perishing with famine, as one single individual; so unselfishly had they divided their family stores amongst themselves that when relief did come, though not till their dire extremity, there was no practical loss of life. Before I close I cannot resist the temptation to tell how my bees have been carrying in meal and uranehave been carrying in meal, and prancing gaily on the alighting boards with their white pellets exposed to the best advantage.

Christiansburg, Ky.

For the American Bee Journal.

#### Honey-Producing in California.

W. A. PRYAL.

No doubt but by this time many of No doubt but by this time many of the Eastern bee-keepers are looking to this far-off "land of milk and honey," as of late years it has been called. Per-haps the reason is partly because here abundant warm rains have fallen all over the State, and the world-renowned honey region has received its comple-ment of the down-pour; in fact, the in-labitants hardly eyer saw so much rain habitants hardly ever saw so much rain visit that section at the right time.

There are now signs, however, that indicate the sun will shine with its usual brightness; that those delightful spring days, which are so peculiar to this fair land, are about to favor us. Let this be the gaze and the beas will soon be flying the case and the bees will soon be flying out by thousands, and the willow blossoms will each and all receive a welcome visit from those industrious insects. Their journeyings will not be confined to the banks of the creeks where the willows grow, but the woodland, where

them through the mild winter safely, The bee flora having had ample rains to insure a most thrifty growth, will bloom for a longer period than it has heretofore, and, of course, will insure

neretofore, and, of course, will insure an enormous yield of honey.

On account of the long continuance of the rain, but few flowers have commenced to bloom. Still the plants are growing, and when they do commence, they will be able to do so in a vigorous they will be able to do so in a vigorous manner. A few of those now blooming are the willows in variety, Eucalyptus globulus, and it is unusually covered with flowers; wild currant, a pretty fair honey plant, but scarce; wild gooseberry; wild blackberry, just beginning; raspberry, ditto; almond; pear and peach; mignonette; horehound, and a few others. All of which give the bees more than they can do to gather the nectar and pollen. nectar and pollen. North Temescal, Cal., Feb. 17, 1881.

For the American Bee Journal.

#### Bee-Men to the Front.

A. W. FISK.

The present may be called "trying times" to bee-keepers of America. Poor times' to bee-keepers of America. Poor honey seasons, hard winters, and the nefarious warfare against the honey producers of this country in the vile adulteration of honey, is indeed trying, discouraging and diabolical. It appears, by the papers, that these glucose scoundrels are not satisfied with adulterating extracted honey, but according to this article that I clip from one of our papers, The Bushuell Record, they are manufacturing comb honey. It reads as follows:

are manufacturing comb honey. It reads as follows:

Many singular discoveries have been made among manufacturers by the census enumerators in the course of their investigations. For instance, it has long been known that dealers are in the habit of adulterating honey with glucose on the plen of this improving its keeping qualities. In Boston, however there is a firm doing a large business in making honey entirely from glucose much in the same way as manufacturers elsewhere make butter from suine and oleo-margarine. The comb is modded ont of paraffine in excellent initiation of the work of bees; then the cells are filled with clear glucose and sealed by passing a hot iron over them, and the product is sent to Europe as our best honey. The busiest linian bees couldn't compete with this firm in turning out honey, any more than could a Eurotas-like Jersey breed compete in hutter making with our det marifullators of lard and tallow.

Now, brother bee-men, I believe the time has arrived when this honey counterfeiting should be stopped; I therefore terfeiting should be stopped; It herefore suggest that the bee-men of this country come up in solid phalanx "to the front," and with Pres. N. P. Allen and the bee-paper editors as leaders, let us agitate the question, educate the people, stir up the press, wake up the country, and vote or petition to Congress until we secure the passage of a law by Congress against the adulteration of honey, sugar, syrup, or food of any kind. Many of the leading journals of our land are battling for the right in this matter. The Burlington (lowa) Harkeye last week expressed itself as follows:

It is time that stringent legislative enactments It is time that stringent legislative enactments are passed, making the adulteration of so many articles of food a criminal offense, punishable by severe penalties. If these things must be done to gratify the inordinate greed of some men, let it be made obligatory on them that the packages containing sparious products so proclaim them, under penalty of confiscation when detected, and the fraud further punishable by heavy penalty. No man has any right to sell a compound of honey and glucose as pure honey, nor has he any right, either moral or legal, to place a compound of batter and lard, still further 'doctored' with drugs, upon the market as pure butter. If adulterations of food are allowed to go on in this way, nurebuked, there is not un article of food known that will not be counterfeited, and oftentimes with substances very hurtful in character.

I am thankful so many are lending their aid and influence in the cause of justice and humanity, but we want the united efforts of honest bee-keepers, and consumers, and fair dealers, to and consumers, and fair dealers, to make a bold front against every adul-terator, and to expose him to the world. In this way I believe the problem can be solved and the evil remedied.

For the American Ree Journal.

## The In-and-In Breeding of Bees.

M. S. SNOW.

Mr. C. Thielmann, in the Bre Jour-NAL, says he has bees which are mostly hybrids, and he does not know where they came from, but there are Italians 5 miles from him. Another says he has no black bees, and his queens must be purely mated. Sc.; another that a neighbor has had some 10 or 15 colonies so many years, breeding in-and-in, but states he manages to keep his number about the same. Breeding in-and-in with bees, I am fully convinced, is not much done. Bees are free rovers and it seems to be their nature or instinct to mate at some distance from the parent hive. Mr. C. Thielmann, in the BEE JOURparent hive.

This question was discussed by one This question was discussed by one of the speakers at a bee convention in N.Y. some years ago. He claimed that in-and-in breeding had a great deal to do with the failures in bee-keeping, &c. He compared an apiary to a yard of towls, in this respect, and that they could be bred in-and-in until entirely worthless. This may be done, forfowls are confined to a particular local ity, but how is it with prairie chickens? what is the reason they do not degenerate and run out? Because they are rovers, like the bee, and are mated by others from some remote part.

I claim that bees will mix from 5 to 7 miles, and if there are 50 or 100 colonies

miles, and if there are 50 or 100 colonies within that distance the progeny of a

miles, and if there are 50 or 100 colonies within that distance the progeny of a certain queen will stand a poor show of mating with drones from its own hive. To illustrate: While living in N. Y. I obtained one of Mr. Langstroth's \$20 tested Italian queens; I reared some 70 queens and introduced them into as many colonies. The next season I had Italian drones by the thousand. My stock of Italian drones were the only ones in the locality, so I had a good chance to test breeding in-and-in. The next season, and even that fall, there were hybrid colonies all over the country, even at the distance of 7 miles, one man had one colony. One man, 5 miles from me, wished me to introduce an Italian queen into one of his colonies. I think he had 6 and I was surprised to see 4 of them hybrids, how they came there he did not know. Others said to see 4 of them hybrids, how they came there he did not know. Others said to me, "I have your kind of bees, but where they came from I cannot tell." All breeders of Italian queens find it

All preders of Italian queens find it very difficult to keep their stock up to the standard of purity. I obtained 5 dollar-queens (Italians) from a breeder in N. Y., which when tested proved to be hybrids, showing conclusively that there were black bees in that section. Osakis Minn Osakis, Minn.

For the American Bee Journal.

## How to Prevent Robbing.

My location for surplus honey is not My location for surplus honey is not as good as some other sections of the State, and from the middle of June to the last of July, from 4 to 6 weeks, there appears to be no honey tlow, and the weather being hot and dry, scorches what bloom is left, soon after June comes in. Onr last rain is in April, or sometimes late in May, and no more, generally, before October or November. All kinds of stock depending on pasture, especially in the hills, suffer at that time. When bees can gather no honey, Italians especially go about visiting for the purpose of plunder, and wee to the Italians especially go about visiting for the purpose of plunder, and woe to the colony that is not strong enough to defend its stores. I have reduced the entrance, covered the entrance with cowchips, wet hay, brush, and, in fact, tried all remedies that ever I saw in print or heard of, without success. While the roblers were helping themselves, the colony robbed was not discouraged, but appeared to be robbing some other, and the queen was laying eggs, to be starved as they advanced to brood; no bees appeared to be killed at the entrance, as willows grow, but the woodland, where the Australian blue-gum (Eucalyptus globulus) has been planted by the hand of man, and which holds out its bounteous chalice for the busy bee to come and sip of nectar deep and sweet.

While the loss in bees will in all probability be great in the States east of the Rocky Mountains, here the loss, if any, will not be quite as bad as it has been other years. Thus it will be seen that our eastern brethren will have to commence the season with greatly reduced forces, while the apiarists in this State will commence operations with more colonies, and, consequently, with more bees. Last season was a good one, and the bees went into winter quarters with abundant stores, which have carried in denouncing it.—Ed.]

and consumers, and fair dealers, to make a bold front against every adulteration and to expose him to the world. In this way I believe the problem can be solved and the evil remedied.

Bushnell, Ill.

So far as it refers to the adulteration of comb honey, it is a false alarm; all bosh! We alluded to this subject more at length on page 44 of the Bee Jours.

NAL for Feb. 9th. We are glad, however, to see the interest being awakened on the subject of food adulterations, and bee-keepers as well as all other honest producers, cannot be too out-spoken in denouncing it.—Ed.]

I exclamged the places of the hives without success, until 1 thought of changing after dark; so while they were robbing I went to all colonies that ap-

peared to be quiet and minding their own business and placed a single stone on the cover, then on those that were getting robbed the worst, 1 placed 2 stones. Then when so dark that no bees stones. Then when so dark that no bees were flying. I exchanged places and put a strong colony on the stand of a weak one. Sometimes I had to repeat this, but not always. Some of those weak ones filled their hives with golden rod honey and robbing was stopped for that source. It was amusing to see the rod honey and robbing was stopped for that season. It was amusing to see the robbers when those strong colonies had fairly awakened, to know that they had callers; they mustered out at the en-trance solid and were ready for busi-ness. The robber seemed to think he had made a mistake. The strong col-ony had not got discouraged; the rob-lars could not force the outrance and ony had not got discouraged; the rob-hers could not force the entrance and the weak colony not in a tighting hu-mor, received the recruits from the strong one, which were a little too sur-prised at the change to interfere with the queen and inmates. Most of the old bees would go to their own stand but in the confusion of things they would gradually be at home in their would gradually be at home in their own hive. I found the plan very suc-cessful, when closing the entrance did not do. I extracted as late as June 10

Last spring my Italians took the grafting wax from my peach grafts. I also observed them gathering the worm also observed them gathering the worm dust from decayed oak wood, and filling their pockets instead of pollen, about Christmas. In the valley 2 miles from here, frost was quite severe, but here the mercury got below 32° only twice; the lowest was 28°. Natural bloom was 2 months behind, owing to early frosts which appeared to drive the sap down to the roots.

Napa, Cal.

For the American Bee Journal.

### Bees Killed by Kindness.

B. F. WHITEAKER.

I commenced the year 1875 with 12 online red the year 1875 with 12 box hives and engaged my brother to hive the colonies in movable frame hives on shares, but the bees swarmed faster than he had the hives ready—one swarmed 5 times in one week. In the fall I had 16 colonies in movable frame and 20 in how high. I prepayed them fall I had 16 colonies in movable frame and 20 in box hives. I prepared them for winter by cutting up a light bedquilt to cover the frames; drove stakes about a foot from the hives all around except in the front, (which faced the south) and packed straw in the spaces and filled the cap with chaff and straw, and covered the hives with straw. In the spring but one colony was living and that was in a box hive. The quilts were laid down flat on the frames, leaving no ventilation. When it became cold the bees died and fell on the bottom board, filling up the spaces between the frames, the moisture fell on the tom board, filling up the spaces between the frames, the moisture fell on the bees and froze solid, closing the en-trance so that I could not open it even with an iron rod. In the corners of each hive was a chunk of ice, running half way up the frames. The bees cut holes through the quilts and when they could, had crawled into the straw and died. This was murder, but such was my experience in 1875-6. experience in 1875-6.

my experience in 1995. Florid, Ill., Mar. 1, 1881.

[We have no doubt your first disasters were attributable altogether to a too rapid increase - ED ]

The North Western Wisconsin Bee-keepers Association will meet at Germania Hall, LaCrosse, Wis., on Tuesday, May 40, at 10 a. m. All interested in bee-keeping are requested to be present. L. H. Pammel, Jr., Sec.

The next meeting of the N. W. Illinois and S. W. Wisconsin Bee-Keepers' Association, will be held at H. W. Lee's, 2 miles n.w. of Pecatonica, Winnebago county, Ills., on the 17th of May, 1881.

J. STEWART, Sec.

TOn account of unfavorable weather the convention at Monroe Centre, Ill., met on Feb. 8, and there being but few present, adjourned to the same place on March 29, 1881.

A. Rice, Pres.

## THOMAS C. NEWMAN.

EDITOR AND PROPRIETOR,

CHICAGO, ILL., MAR. 16, 1881.

#### Watchman! Tell us of the Night.

Can you not recommend some reliable prophet, who will prophesy good weather soon? The storm is terrible; not a read in the county is passable for half a mile; the drifts are as high as the fences, and the snow full three feet on the level.

level.

Bees are getting uneasy, and must have a flight soon. Many report heavy losses, even now; others complain that all are sick with dysentery. In my home cellar, out of about 275, 4 are slightly affected, the baiance are apparently in good condition. My outside apiaries fare worse. Two weeks ago quite a number had the dysentery slightly; I should judge about 8 or 10 per cent. How they now are I cannot tell; certainly, no better. I believe that they can stand it a month longer, and my can stand it a month longer, and my home apiary 6 weeks, but that is the

We are all afraid that Vennor's prophecy of I1 feet of snow will yet be realized, unless some one can be found to contradict it. Eleven feet of snow now would last us until all our bees had died a natural death from old age. Help us out of our trouble, if you can

GEO. GRIMM. Jefferson, Wis., March 3, 1881

It was with much pleasure we noticed, in last Thursday's Associated Press dispatches, evidences of Prof. Vennor's reformation. He undoubtedly has become convinced that the realization of the eleven feet of snow attributed to his prophecies, would not only cause much suffering and privation with the majority of humanity, but work serious and permanent injury to the country itself. He has relented, or probably been bribed by Mr. McColm's liberal offer in the BEE JOURNAL of March 2, page 69, and now premises us better weather in the future. His latest prediction is a reasonably early, warm, dry spring, cool, pleasant summer, and late, dry fall, followed by a mild and pleasant winter. Of course, he promises abundant crops, and a satisfactory and remunerative harvest.

But without any further reference to Prof. Vennor, and without laying any claim to the "spirit of prophecy," we believe the coming season will be a very satisfactory one to those bee-keepers who may be prepared to profit by it, and who have the industry and intelligence to make the most of it. The winter of 1879-80 was very mild and open, the scarcity of snow left the earth's surface exposed alike to the freezing temperature of night, and the pleasant sunshine of the balmy days; spring-like showers were of frequent occurrence, and heavy rains accompanied with thunder were so numerous that they ceased to create surprise; while the weird spring-music of the frogs was a familiar sound every menth, and nearly every week, throughout the winter. The alternating cold and heat "threw out" the roots of the perennial plants, breaking off the long, deep-reaching taps and killing the rootlets; hence the frequent expression, "but little white clover in bloom, and ne honey in the blossoms." The honeyproducing annuals done but little better, owing, we presume, to the germi-other business connected with bee-keep-

nation of the seeds in mid-winter, and ing, and this would suffer if close attenthe frequent frosting of the tender tion was given the migratory system. sprouts before spring set in. Thus, the summer and fall bloom was limited, and no provision having been made to supply the short-comings of nature, bees entered upon an unprecedented winter with a poor supply of good—or a good supply of poor-honey. The many empty hives in the country this spring is the result.

The past winter, whatever else may be said of it, has been propitious for the honey plants. Cool weather in this latitude set induring October; vegetation was checked in the perennials and biennials; the ground was frezen in November, and it was overspread with a mantle of snow quite early in the season, which has constantly held the roots of the perennials in position, and prevented the seeds of the annuals from unseasonable germination. The stand of white clover last fall was good, and mostly of quite recent growth, which should bloom profusely this season, and will only need heat and favorable sunshine to develop the nectar. The causes enumerated will also tend to confine the vitality of the linden trees to the roots. to be drawn out in profuse foliage and bloom by the genial rays of the summer sun. The numerous variety of flowers we believe will gratify the eye of every lover of the beautiful in nature, and well reward the labors of the painstaking bee-keeper. That the price of honey will be remunerative next fall no one can doubt, in view of the lessened competition, owing to the heavy losses the past winter and the many who will utilize the bees they have left to refilling their empty hives.

It would take more space than we can give a single article, to explain why we have much confidence in Prof. Vennor's latest prediction, referred to abovethough perhaps "the wish is father to the thought." We feel confident many of our readers will cordially unite with us in welcoming the better time coming.

## Migratory Bee-Keeping.

Why do not the enterprising bee keepers of these parts go South with their bees, and wait till the March "blizzards" are over? Seems to me the the expenses of the trip. How much does a colony need in those parts to winter on? Would there be any prospect of obtaining any surplus down there before the season opens here? These and a dozen other questions I am vainly speculating upon. Are Messrs. Bingham and Perrine the only ones that have tried the migratory plan. I believe neither of them was successful; at any rate, they have abandoned it. Probably they could not give it the necessary attention. The loss of larvæ in shipping seems but trifling compared to the gain in young bees. Considerable the gain in young bees. Considerable damage may be done by combs breaking but wired frames would obviate down, but wired frames would obviate that difficulty. Is not wired foundation (wired in frames) the only kind that can (which in frames) the only kind that can be depended on under all circumstances? You report in the October number, 1880, page 468, that the Northwestern Convention disapproved of wired foundation. There were but few present that had given wired foundation a fair trial, and if I am not mistaken, they were strongly in favor of it.

H. W. Funk.

Bloomington, Ill., March 5, 1881

The first question is difficult to answer, as enterprising bee-keepers, like the balance of humanity, are generally governed by metives of convenience

The amount of honey required to winter in the South is much less than in the North, but the quantity is governed by contingencies, as would be the question, How much honey will a colony obtain in the South in a season? Usually bees obtain considerable surplus in April and May, in some localities. Mr. Bingham, we believe, abandoned the migratory system on account of excessive freights, while Mr. Perrine met with a series of disasters from the first which would have discouraged any one. Mr. W. O. Abbott was engaged last season with a floating apiary on the Mississippi river, from which large returns were anticipated: but as nothing definite has been made public since the close of the season, we suppose it was not a success. Others have tried Southern wintering, but we have no data upon which to base conclusions, except the fact of its abandonment. The trouble has not been so much from destruction of combs, as the expense attending the removal.

A private letter from a gentleman with several hundred colonies of bees, located a short distance below Memphis, Tenn., dated March 5, says: "My colonies are mostly very strong; they are bringing in 5 kinds of pollen; many are clustering in front of their hives; most of them had large quantities of honey left over, and I could extract an average of 15 lbs. per colony with profit to the bees. Bees here are given no attention in the fall, but are left on the summer stands, sometimes with the second story over them, and often with only a honeyboard. Frequently there are entrances at front and rear, and wide cracks in the sides from which bees pour out, but disaster never overtakes them except from starvation."

If a necessity exists for wires in foundation, then perhaps the wired frames are best. That but few of those in at tendance at the Northwestern Convention "had given wired foundation a fair trial," was undoubtedly owing to the fact that the great majority of those present had never experienced the necessity for using wires; and it might be difficult to convince a considerable minority of the bee-keepers in the country that wired foundation is even desirable for general use. Of course, for special purposes, such as migratory bee-keeping, shipping in summer, etc., where not to be transferred from the frames. wired-frames might be very desirable.

#### Interesting Letter from Ceylon.

Through the courtesy of Mr. D. A. Jones, we are permitted to publish the following letter. Anything relating to the peregrinations of Mr. Benton in the far East, and any discoveries of new races of bees he may effect, will possess a great attraction for our readers. His next letter, from Singapore, will be awaited with interest.

I found on examination that every queen was alive upon my arrival in Pointe de Galle, though some of the Pointe de Galle, though some of the nuclei were greatly depopulated, owing to the death of many bees, and would not have lived to reach Java had I not gotten off in Ceylon. By the next steamer I go to Singapore. I have made every effort to secure bees here, but none are kept in hives in those ports I have visited, and I do not think in any sort of the Island. port of the Island

Of those found in trees few can be secured, because the trees are valuable cocoanut palms, and the entrance holes

are in the trunk of course, and are very small. I have obtained three hives only of the small bees, having also spent some time fixing up the bees I brought some time ixing up the bees I brought with me, and trying to find the large bees, to say nothing of searching for some place where bees could be purchased in hives or pots. The natives are far worse than Cypriotesto get along with and accomplish anything. They seem to tell lies simply for the sake of civing an answer where no recurriary giving an answer, where no pecuniary gain could come to them. Again, they seem to wish to avoid saying "I do not know," when the Lord knows it would be the most appropriate thing for them to say in ninety-nine cases out of a hun-The result is that it is hard work to sift the statements made by the natives, and Europeans—nearly all English-know absolutely nothing of value

to us.

The new bees, which I think are also found in India and many of the East India Islands (in which case East India India Islands (in which case East India bees would seem to me an appropriate name), are real beauties. The workers are  $\frac{3}{8}$  of an inch long, and build worker comb  $\frac{5}{8}$  of an inch thick, 36 cells to the square inch. The drone comb is exactly the size, and like worker comb made by the base already in Europe and Arreit the bees already in Europe and America. The workers are brown with a very ca. The workers are brown with a very ringed abdomen, the bands to the tip of the body being broadly marked with yellow, and thorax very fuzzy, with a large shield between the wings; the drones are black, inclining to a blueblack, and are 12 of an inch long; the queens are leather-colored, and large compared with the workers. These bees are very setting wonderful breaders are are very active, wonderful breeders, reg-ular little beauties, and can be handled without the least smoke, scarcely ever offering to sting. It is a pity I cannot get more of them during my stay.

I am determined to find out whether

Apis dorsata is to be found here, if time will permit, and if two more races I have heard of here really do exist. I am now where a few shillings of railway fare will bring me to the interior of the Island. More by next mail, with sam-Island. More by next mail, with samples of bees and comb.

I have had a horrible time getting

stung with large hornets while in the jungles. It laid me up for one whole day. These are fearful fellows, worse than those in Cyprus. F. BENTON. Colombo, Ceylon, Jan. 24, 1881.

There are five Wednesdays in March-hence, the next number sent to Semi-Monthly subscribers will be No. 14.

We can supply but a few more of the back numbers to new subscribers. If any want them, they must be sent for seon.

One letter sometimes makes quite a difference in the meaning of a sentence. Mr. L. James calls attention to an error in his article on page 34, in the 4th line from the bottom-the word hiving is there given as "hiding." As the sense indicated the word required, perhaps it was not generally noticed.

The past week has been noted for snow storms, not only in America but also in Europe, where a winter of unusual severity is reported, with deep snows and steady frosts for months together. This winter will have a place in history, as being among the most severe as well as of the longest duration. Not alone have the bees suffered by it, but cattle, sheep, hogs, etc., have perished by the thousand from the prevalence of blizzards and deep snows.

Several bee-keepers in this vicinity are considering the feasability of holding a convention in Detroit this spring. The law in regard to foul brood, which is about to be passed, makes an organization necessary. It is desirable to know how many would favor the enterprise. Will such please send me their address. A. B. Weed. No. 75 Bagg street, Detroit, Mich.

# SELECTIONS FROM

Wintered Well.—I have wintered 40 colonies of Italians on the summer stands; they have wintered well.

James H. Davis.
New Holland, Pa., March 8, 1881.

Mortality Reports.—It seems to me that the only way of profiting by the experience of bee-keepers throughout the country, this exceptionally severe winter, is to reduce their reports to a tabular statement. If they could be induced to send in these reports, in the form of brief answers, to questions like the following, we could read the history of the past winter on a single page of the BEE JOURNAL, and learn from it lessons of scientific value. I mean such questions as these:

1. How many colonies did you winter?

1. How many colonies did you winter?
2. Where? (out doors or in cellar.)
3. What hive did you use?

4. How did you prepare it?
5. What entrance was left open, bottom, top, or both?
6. How late did the bees breed?
7. How many the of home.

7. How many lbs. of honey were they allowed to keep?
8. When did they have their first

dight?

9. How many colonies did you lose?
С. F. Ккоен.
Hoboken, N. J., Mar. 5, 1881.

[It would be difficult to get up a reliable report of this kind for many reasons, chiefly, perhaps, the following: 1st. Spring does not open simultaneously all over the country, and by the time the last were heard from, the table would have lost its interest; 2d. Many are sensitive, and prefer not to give their experience; 3d. Many have partially reported already, and would scarcely care to do so again. We agree with Mr. Kroeh, a table of that description would be invaluable for reference; but it is difficult to obtain.-ED.1

Nineteen Weeks' Confinement.-Bees have at last had a purifying flight after 19 weeks' confinement. I find 28 dead from 153, I packed in chaff. Temperature has been below zero 7 times, and as low as 17° below, this winter. A few of the remaining colonies are weak and or the remaining colonies are weak and may die yet, but nearly all are strong for this season of the year. One has had dysentery since Dec. 15, but is alive yet, with a fair prospect of getting through.

Burger Mich. March 10 1821. Banger, Mich., March 10, 1881.

Wintered Safely.-We had a very poorseason last year and the winter has been very severe. I began the last season with 1s colonies, increased to 34 and obtained about 500 lbs. of surplus. I wintered in the cellar, and lost 3 colonies with dysentery. My bees had a cleansing flight about 2 weeks ago and I think we will have no more losses this winter. winter. There are quite a number of bee-keepers in this vicinity, but most of them report very heavy losses, some having over 100 colonies and losing nearly all. We are very much pleased with the Weekly BEE JOURNAL, and think it for surgious over Monthly. think it far superior to any Monthly. L. E. Welch.

Linden, Mich., March 8, 1881.

A Slim Llving.—I prepared 21 colonies on Dec. 1st, for wintering on summer stands. Hives were sitting on 4 inch-blocks, and the colonies were all strong. I placed woolen blankets over the tops of the frames, then the honey-boards and covers, and left them for the winand covers, and left them for the win-ter—my usual way. Always heretofore they have come out bright. Feb. 22(1) felt uneasy about them, and being a bright day, I opened the hives to find 1) dead out of 21 colonies, and the remain-ing 10 mask. The hives were folled

not discouraged. If I had to make a living from bees it would be slim. I can learn more in I week about taking eare of bees from the BEE JOURNAL, than 1 could in 1 year without it.

EDMUND DELAIR.

Oketo, Kan., March 1, 1881.

Honey Sections.—In the BEE JOUR-NAL of March 2d Mr. Heddon says he prefers a section that he can press to any angle and have it solid, but 1 fail to see that any other angle than square is of any advantage. Again, Mr. H. asks, "Is it not better to wait and see which goes into general use?" Perhaps the following figures may show which has gone into general use, at least with has gone into general use, at least with our customers. I make any kind that are wanted, and therefore the figures will show which are the most desirable. In 1879, the first year that the one piece sections were put upon the market, and at a higher price than other kinds. my

sales Were:
104,578 one piece sections.
124,058 dovetailed.
38,270 nailed.

In 1880, the following are the figures:

233,898 one-piece sections. 47,980 dovetailed. 50,950 nailed.

According to Mr. Heddon's test, there fore, the one-piece sections are the most desirable, because they have gone into general use.

G. B. Lewis. general use. Watertown, Wis., March 8, 1881.

Bees in Good Condition. - The Weekly BEE JOURNAL is a welcome visitor and is the first paper I read when I return is the first paper I read when I return home on Friday evening. It is a friend that introduces me to my fellow bee-keepers, and their manner of manipu-lating our pets. My bees are in good spirits, yet they had but 2 flights this winter. I have them packed in a shed in new Langstrath bives, manipulating in new Langstreth hives, manipulating sides. They are 6 inches apart and sides. They are 6 menes apart and packed all around with straw, excepting the fronts. They face the south, with a division board on each side of the frames, leaving a dead air space.

JOHN W. STURWOLD.

Haymond, Ind., Feb. 7, 1881.

Wintered Without Loss.—I have kept bees for 7 years and my greatest trouble has been wintering them, but I think I have that perfect now. I winter on summer stands packed in chaff. Last fall I had 72 colonies, and on Feb. 9 all were right. I think I shall have to feed them. Last fall some had 15 lbs and Last fall some had 15 lbs. and them. others 25 lbs of honey; that is if bees and comb weighed 10 lbs. The combs were all new, and it may be that 10 lbs.

was allowing too much.

GEORGE WICKWIRE.
Weston Mills, N. Y., March 4, 1881.

Mourning for the Bees.—It is lamentable to hear the reports throughout this country. Some have lost all; others all but 1 or 2. I think about four-fifths of the bees are dead through this country as nearly all left their bees unprotected as nearly all left their bees unprotected, they had to suffer losses. But I think the present winter will in part decide the best methods of wintering. I started last spring with 4 colonies, increased to 6, but obtained no surplus. In Sept. I bought 2 Italian colonies which are doing well. I packed 2 in chaff and 6 I put into the cellar, but 2 of these died, I starved, and the other had the dysentery. Those packed in chaff had a good flight on Feb. 26. Those in the cellar had no flight since Nov. I. The weather is now breaking up, the snow has nearly all gone, and the roads are muddy. I am highly pleased with the Weekly Bee Journal. I could not be persuaded to do without could not be persuaded to do without t. H. CRIPE.

North Manchester, Ind., Mar., 8, 1881.

Wintering.—My experience of over 25 years in trying all modes of wintering is as follows: On summer stands, and in the cellar for 10 years; I then built a house to winter in, used that 2 years and then abandoned it. The last 3 years I have been using the chaff hive and winter on summer stands, with the least loss of any way I have tried. My bees had a splendid fly on the 11th, it being the first chance for them since with frost and ice, and blankets wet with water; 5 out of the 11 dead had Italian queens, which I purchased from Mr. A. H. Newman last summer. I am Italian distribution of the standard in the least less of any way I have tried. My bees had a splendid fly on the 11th, it being the first chance for them since the 8th of Nov. I think they will go through all right now unless we have a

very late spring. I prepared 148 colonies for winter, (123 in chaff hives and 25 in the common box hive.) I have lost but one in chaff hive yet, and 10 in the box hive already, and doubt if one-half of what are left will see the middle of April. I wish to congratulate our editor on the success of the Ber LOURNAL. itor on the success of the BEE JOURNAL. I have received it regular since assuming its new form, and think it just splendid, and if I had but I colony of bees I would try to take the Weekly BEE JOURNAL to aid me to make a success of that I. I hope the editor may be liberally supported by the beetless of the supported by the keepers of America, for I believe with his experience and that of his able contributors, he can give us a paper that we cannot afford to do without. J. M. France.

Auburn, Pa. Feb. 24, 1881.

on account of queenlessness, weakness, etc., to 45, all in first class order. I bought 50 colonies in old-fashioned Langstroth hives; they were wintered in a good cellar, and were, with a few exceptions, weak in bees, combs in bad exceptions, weak in bees, combs in bad-order, short of stores, and badly man-aged the preceding season. I united them down to 27 before I moved them. At the beginning of hency harvest (basswood bloom) I doubled up to 15, so that when the honey season opened I had 60 first class colonies, and obtained had 60 first class colonies, and obtained 3,500 lbs. of summer honey. I extracted only once. 1 increased by natural swarming to 8s, and at the close of the season doubled up to 74. I have lost 1 this winter through my own fault. I winter out-doors, but would winter indoors if I had a proper place. I sell doors if I had a proper place. I sell nearly all my honey to the consumers, but confess this is a vexatious way of disposing of it; it is the most annoying gart of the business; in fact, I feel disgusted when I think of it. People cry fraud, fraud, when there is no fraud; but when a spurious article is offered, they swallow it as quietly as desired.

GEORGE W. HORNER.

Dubuque, Iowa, Feb. 15, 1881.

Prospects Better.—This has been a fine day; my bees had a cleansing light to day. They are all alive and strong, and seem to be in splendid condition, with plenty of honey and perfectly dry. I think all the dauger is over with them now. I am in favor of double-walled hires but not packed with chaff for I now. I am in favor of double-walled hives, but not packed with chaff, for I have noticed that where there is chaff there is frost on the inside wall. I prefer a dead air space, for then it is always dry. What is the use of changing black bees for Italians, if Mr. Loucks, of California, can get so much honey from the black bees, they surely must be the "boss" bees? I think we had better take our bees to California. had better take our bees to California, where milk and honey flows.

DAVID HOHENSHELL.

Collins, Ill., March 6, 1881.

All Alive.—My bees are all alive and in fine condition. They were wintered out of doors, in shed, packed around with straw, but open to the east.

J. R. MEAD.
Wichita, Kas., March 7, 1881.

Winter yet in Kentucky.—Bees are wintering very badly here, and 2 of my neighbors have lost all they had. The ground is covered with snew, and looks as much like winter as it did a month ago. Covington, Ky., March 5, 1881.

No Surplus nor Jucrease.-This has Ao Surplus nor Increase.—This has been a hard winter on the bees. I think all that were not protected and those partially protected will die. There was no surplus nor increase here worth mentioning, last summer. James Nipe.

Spring Prairie, Wis., Feb. 26, 1881.

Great Loss of Bees. - The bees in Mc-Donough county that were wintered on the summer stands are nearly all dead. These in double-walled hives, and those Those in double-waned inves, and those packed in straw, dying the same as those in single-walled hives. My loss is about 95 out of 100. S. II. BLACK. Sciota, Ill., March 5, 1881.

Bees in Prime Condition.—1 have 110 colonies in the cellar in prime condition. Nearly all bees out doors are dead. C. H. DIBBERN.

Milan, Ill. Mar. 9, 1881.

Paris tireen.—It is not very good for bees, as I had an opportunity last spring to find out. I have in my garden a to year old plum tree that never perfected year old plum tree that never perfected any fruit and knowing that Paris green would kill bugs I thought it might also kill the "little turk," or Curculio. Acting upon the suggestion I mixed some Paris green in a watering can and put up through the branches of the tree a long ladder, from the top of which I sprinkled the whole top of the tree just before dark, and a day or 2 before the bloom went off. Next day afternoon as I was passing through my bee yard I was very much surprised to see on the ground a good many bees in Vexatious to Sell Honey.—I only realized \$300 last year from my bees. I put 50 colonies in winter quarters in the fall of 1879; lost none, but doubled up the conclusion that they had gone to count for. I came at last, however, to the conclusion that they had gone to the plum tree in the morning before it was dry and partaken of the poison. I lost a good many bees but I have learned this lesson, "never to put Paris green on trees when in bloom;" still 1 am satisfied that by sprinkling or syringing 2 or 3 times, when the plum is in its incipient state, it will insure a crop. Who will try this spring and report? GEO. THOMPSON.

Geneva, Ill.

Making Progress.—Although behind some other States, yet we have made some progress. Bees seem to do best in the newer counties, where the timber has not been cut off. It might be supposed that the northern portion of this State was not favorable for bees, but Aroostook county, in the extreme north, produces nearly as much honey as all the other 15 counties, and the honey is put up in the most marketable shape: put up in the most marketable shape; but I fear the bees are not protected as they should be in this northern climate. We have had a cold winter, and the loss has been very great. I winter my bees in the cellar with success, and obtain much pleasure, as well as profit, from the time I devote to them. The Weekly BEE JOURNAL is my constant companion. ISAAC F. PLUMMER.

Augusta, Maine.

Not Discouraged.—Should I be persudded to give up the business of keeping bees for profit, I do not know what I could find that would pay better. I have 25 colonies in good condition and every one in this town wants honey, and I shall try to supply it to them.
Osage, Iowa. Charles Follett.

Lost but 4 out of 273.—My bees are wintering well; I have lost but 4 out of 273 colonies, wintered on the summer stands, packed with sawdust and planer than the stands. shavings. It has paid me to advertise in the Weekly Bee Journal. I have all the work I can do. A. E. Manum. Bristol, Vt., March 9, 1881.

Dead Bees in the Cells.—I took 6 combs out of 2 hives in which the bees died, that had plenty of honey in the 2 outside frames. In every cell of the 3 middle frames is a dead bee. I tried to pick them out with a pin, but gave it up for a bad job. Is there a way to clean them? Can I use the combs again next spring? Please let me know in next JOURNAL. Please let me know in next Journal.

John W. Sturwold.

Haymond, Ind., March 11, 1881.

[You will find our method given in answer to Mr. Phillips, page 86 of this number. The combs can be used again this spring.-ED.]

Progressing.—My bees are getting along well. I have lost 3 weak colonies that were left unprotected; but it was my own fault. A hive peddler was in this section this winter selling hives without frames. I showed him my hives, similar to the Langstroth, and he took the measure of it, and said I was "well fixed" for bee-keeping. He never said a word about selling his hive to me. I do not know how many he sold.

John Boerstler.

Gilead, Ill., Feb. 26, 1881.

Gilead, Ill., Feb. 26, 1881.

to make the best use of the combs left, summ as they are mostly new. Some are moldy, what shall I do with them? Some left, what shall I do with them? Some left, on exts of the cells are full of dead bees, how it remains the moths out of the combs until I can lown a nse them? An answer to these questions through the Weekly, at an early all of day, will no doubt benefit many new beginners.

O Profits nners. O. PIILLIPS. Emporia, Kans., March 2, 1881.

[When your colonies are strong in the spring, give the moldy combs; they will soon utilize them, if not given too fast. The combs with dead bees should be kept in a dry place, and after the bees have become dried and shrunken, you can easily shake them out of the cells. If moths get in the combs, treat them in the manner suggested by Mr. Doolittle, page 74, BEE JOURNAL of March 9th. One pound of sulphur, however, to each 100 cubic feet, seems a large amount; this would require 10 lbs. for a room 10 feet square. We have had no experience in sulphuring combs, but think 1 lb. would be sufficient for 1,000 cubic feet, in a close room.—ED.]

Palestine Bees.—We are having a hard winter on bees; they have not had a fly since last Oct. 28. Bees that were here kept in old-style boxes are nearly all dead, many that were packed in chaff are dead or have the dysentery, and are flying out on our coldest days, and of course never return. My bees that are in chaff tenement hives are in that are in chaff tenement inves are in the best condition of any I have seen. My Palestine bees are standing the lonely confinement in the hives better than the Italians; they are quieter, and than the Italians; they are quieter, and do not fly out so much and get lost on the snow. I much like the Weekly BEE JOURNAL, and when I got the JOURNAL of Feb. 2d out of the office I felt like grasping the hand of the Editor, and having a shake, but alsa it was not flesh and blood, but a very good likeness. Many thanks for giving us chance to view it. I. R. Good.

Napanee, Ind., Feb. 2, 1881.

Honey as Medicine.—I wish to compile for publication an exhibit of the medi-cinal qualities of the various kinds of honey, and I shall be obliged for any facts sent me on the subject. Chaff-packing seems to be ahead here this winter, but I notice a great difference in the wintering capacity of several colonies. All of mine which were devoted to the production of honey are doing well, but I have lost by excessive early breeding, and some that were used to rear queens. They had no flight for 4 months.

They had no flight for 4 months. Onethy Not Mayal, a less than the wine production of the production

S Ave., Omaha, Neb., March 9, 1881.

Gathering Pollen. -- Last season proved a splendid one for bees. Each colony averaged 72 lbs. of surplus sweet honey, and from 20 to 40 lbs. of bitter. My bees are blacks, and to-day are out gathering pollen and some honey.

E. P. MASSEY.

Waco, Texas. March 1, 1881.

Auxlous for Spring.—The Monthly was good, but a more frequent visitor, in the shape of the Weekly is better. It brings fresh news, ready for use. I spent an hour in my cellar, last evening, examining mybees. I was heart sick at the condition in which I found them. I had about 40 colonies in the fall; at least one-half of them are dead. I have an excellent cellar, especially for my least one-half of them are dead. I have an excellent cellar, especially for my bees, and have not lost a colony before for 5 or 6 years. I began to think that losing bees in winter was an unneccessary thing, but I see that I was mistaken, for my bees did not lack for care in any particular. The death of mine is from dysentery. The small amount of boney collected in this vicinity last year was a very poor quality, as is seen from the fact that it has not candied during the winter. I extracted about 300 lbs, and put it away in glass jars, and it looks like so much New Orleans molasses. My friend, Mr. Bischoff, had

Moldy Combs, Etc.—Having lost a few about 40 colonies in the fall; all are now colonies of bees the past winter. I wish dead but 6. They were left on their to make the best use of the combs left, summer stands. Mr. B. is lonesome dead but 6. They were left on their summer stands. Mr. B. is lonesome and wants my bees put in his apiary next summer to keep him company, but it remains yet to be seen if 1 will have any left to keep up a humming in my own apiary. I met Mr. Gardener, of own apiary. I met Mr. Gardener, of this city, the other day, and he reports all of his 16 colonies dead. Several other bee-men have told me that but few, if any, of their bees are alive. Winter still holds on with an iron grasp. Our bees so much need a cleansing flight. I am anxiously waiting for some warm days.

1. P. Wilson. Burlington, Iowa, March 4, 1881.

> Died of Disease.—1 have lost about all the bees I had, yet I love to hear of other's success in the bee business, and read of others'way of management; but an convinced that my bees died of some disease, the same as Mr. Carver reported from Greencastle, Indiana, although bees have not died so universally throughout this country as mine have. I have the hives and combs left, have. I have the myes and comes with lots of honey in them; these I can believe nerhans, or melt sell for something, perhaps, or melt them into wax, or get a few colonies of bees to begin anew, but it is very poor encouragement to put much stock in bees, the way it looks now.

Cyprians Ahead. - Bees doing well; they are commencing to work on plum-bloom; they have brood in all stages. In an average of over 30 colonies of Cyprians, they are farther ahead in brood-rearing than the Italians. The latter have had the same chance as the former. Am very some for queen-rearing. J. H. P. Brown Am very busy now, preparing

Augusta, Ga., March 2, 1881.

An Early Season.—I see from reports in our new Weekly JOURNAL that bees are dying throughout the north and west more than usual, from short stores are the control of the season of the and intense cold. I may say that we have had an unprecedented cold winter here, the thermometer at one time ranged, for a few hours, as low as time ranged, for a few hours, as low as 18 above zero, but soon struggled back to about 25 below. Last fall our bees gathered a full supply of fall honey, and none will die from cold or starve out that are worth saving. The winter being wet, white clover is coming out very thick over the ground; maple, elm, plum and wild cherry are now in bloom, as well as heads of white clover are mushing out their lovely forms to the pushing out their lovely forms to the genial sun. Bees usually work on white clover here by the 10th of this month; but this year our honey season will be much later. May the "new departure" prosper and lead us forward to perfection.

J. W. Winder. on. J. W. Winder. Thibodaux, La., Feb. 10, 1881.

[Mr. Winder enclosed us some white clover blossoms of this year's growth. The sight of the modest flowers is re-

freshing, while from our office windows the earth looks bleak and gloomy with

its deep mantle of snow.--ED.]

Gone back on him.—1 had 30 colonies bees—most of them Italians—last of bees—most of them Italians—last fall, in Langstroth hives, packed in this way: The ends of my hives are double-walled, and the sides are made double in winter by the use of division boards, in place of 2 frames, leaving but 8 frames. I then use a crate made of laths, which sets down around the hive so as to leave a space of about 8 inches for packing between it and the hive on the sides and back end. This space I fill with a packing of fine straw and leaves mixed, and packed hard when just a little damp. Then strips of board are fitted so as to protect the top of the straw from rain or snow; next a blanket

the 5th inst., there has been no day warm enough for bees to fly for some mohths. Many did come out, even on the coldest days, but of course could live but a few moments out of the hive. the but a rew momens out of the live. I let them entirely alone, except to see that the entrances were free, until day before yesterday, when it was warm enough for bees to fly. I looked them over and found only twelve of them alice, only tof them are in good only. alive; only 1 of these are in good condition, the others are weak and the hives a good deal soiled. Now, what hives a good deal soiled. Now, what puzzles me is this. They were all, apparently, very nearly alike last October, and now 4 of them are in perfect condition while all the others were bad. Now, while the four exceptions out of 30? I am glad for them, but would like to understand the reason. Can you tell us, Mr. Editor? They have evidently not been cold, and have had plenty of honey. In the dead ones I have examined I find brood in a hatching state, with half or more of the cells empty, indicating that young bees had hatched. I attribute the disaster to long confinement, but why the 4 exceptions? I say amen to all the compliments you publish while the four exceptions out of 30? to all the compliments you publish from your subscribers for the BEE JOURNAL. D. K. BOUTELLE.
Lake City, Minn., March 7, 1881.

[Probably during some of the milder days of winter the bees became scattered in their hives, the weather suddenly changed, and they perished before they could form their cluster on

honey, and thus starved.—ED.]

From Florida.—The BEE JOURNAL is at hand; we do not know how we could do without it. The past has been a very good honey season here. We have 255 colonies of bees in Langstroth have 255 colonies of bees in Langstroth hives. Some are Italians—we like them as honey-gatherers, but they are crosser than our natives. We obtained 850 galls, honey, and 500 lbs, wax. The latter we obtained from about 90 hives which we transferred. We think apiculture will pay here with good management. We extracted from one colony, 29 Langstroth frames well filled agement. We extracted from one corony 32 Langstroth frames well filled with honey. Our apiary is located on a "gum" swamp, 5 or 6 miles wide and 15 or 20 miles long, which is our main honey source, and blooms from April 15 till May 15; we also have many other honey producing flowers. We have a vine which grows in the swamps and che which grows in the swamps and yields a great deal of amber-colored noney. We inclose a sprig—please give the name. Alderman & Roberts.

Wewahitchka, Fla. honey.

[The vine you send is commonly known as snow vine, and is quite abundant in several of the Southern

States.—En.1

Bee Feeding.—I have thus far used he "bag feeder," of our friend Prof. Cook, with this addition: I have a long Cook, with this addition. I have a long tin tube, shaped like the handle to a water-dipper, long enough to reach through the bag of chaff and empty into the bag: then, with the aid of a funnel, I can daily place the warm food within reach of the bees without disturbwithin reach of the bees without disturbing them or letting out the heat—so precious in early spring to a depleted colony. Have never tried the Professor's "Perfection"—thought I saw objections to it. If any of our more experienced bee-keepers have devised a "better way," please tell me through "our" Journal. E. M. R.

Flint, Mich., March 1, 1881.

Introduced a Queen.—Bad luck to bees in this valley of the Ohio. Of 32 colonies in Langstroth hives, 18 now remain, and the 4th day of March a perfect "blzzard" all day, so I fear I will lose more from spring dwindling. I found, one day in February, all the bees dead but two, and the queen nearly gone, in one hive, but plenty of honey. I had a queenless colony, and laid these 3 hees on the frames to see if they would come to life; they became warm and 3 hees on the frames to see it they would come to life; they became warm and erept down among the bees. The next warm spell 1 looked, and the yellow queen was safe among the black bees. A novel way to introduce a queen in February.

G. W. ASHBY.

Valley Station, Ky., March 5, 1881.

Loss 88 per cent.—The loss of bees in Wayne and Randolph counties is heavy—about 88 per cent. Our bees had a fly Feb. 26th, the first for 111 days. had a fly Feb. 28th, the first for 111 days. We have reports from 1400 colonies November count) and March 1st linds them all dead but 171. The Italians have come through better than the blacks. Those packed in chaff on summer stands have wintered better than any other mode in this locality. There is a great call for bees here by parties that are wanting to start again. Our that are wanting to start again. loss is 4 out of 15 colonies, all in cha hives. M. G. REYNOLDS, Williamsburg, Ind., March 7, 1881.

First Year's Experience.—Bees done borly here last season. There was an poorly here last season. There was an abundance of bloom, but too much rain. I sowed I acre of buckwheat; while this lasted my bees stored more while this lasted my bees stored more honey than at any other time in the season; I think it an excellent honey plant. Pumpkin blossoms yield considerable honey; would it pay to plant them all over a field of corn? My bees are packed in chaff, and they are all in good condition at present. They have are packed in chan, and the good condition at present. They have not had a flight since the 1st of Nov. Success to the Weekly Bee Journal; I like it better than the Monthly.

WM. HAGAN.

Holly, Mich., Jan. 18, 1881.

|Pumpkin blossoms yield a rich, but strongly flavored honey; we think the pumpkins would be remunerative for their cultivation to feed to stock, and that the honey obtained from the blossoms would be a net profit.—ED.]

Summer a long way off.—This winter has been, so far, the most severe known for many years in this part of the State. Snow-storm has followed snow-State. Snow-storm has followed snow-storm, and cold spell has followed cold spell, until now there is more snow on the ground than we have had altogether for 6 or 7 years. And the poor bees! how have they fared through all the snow and cold? Badly, I fear from the reports I hear every few days; but so far as heard from, where they were properly cared for, either in cellar or on summer stands, they are doing quite well; but summer is a long way off.

HARRY G. BURNET.
Blairstown, Jowa, March 5, 1881.

Blairstown, Jowa, March 5, 1881.

A Little Discouraged.—I am a little discouraged this spring. I put 54 colonies into winter quarters last fall and nes into whiter quarters ast tan and now have but 23, and some of them are weak. Those in my bee-house suffered the worst. I had 20 colonies on the summer stands, packed with cut straw, and lost 6 of them by dysentery and starvation. If bees are strong in numbers and have plenty of honey, I can see that there is no danger of loss. Last see that there is no danger of 10ss. Last season it was so dry here that the white clover dried up, and the bees could get but little honey, and what they did gather was very dark. I am glad to receive the BEE JOUNNAL weekly now; the news comes and seems so fresh. I have it will be well supported. hope it will be well supported.
J. W. Rikie.

Mont Clair, N. J., March 6, 1881

Why Did They Die 4—Last fall I put my bees into a dry cellar; some of them had 75 lbs. of honey, and in 4 or 5 weeks there were many dead bees. I cleaned them up but in a few weeks more they all died; what was the cause of this? Over 80 per cent, of all the bees in this vicinity are dead.

R. L. HOLMAN.

Springfield Ohio Feb 19 183. Springfield, Ohio, Feb. 19, 1881.

[Your colonies were strong, had a large quantity of honey, and the cellar was too warm; they commenced breeding, became uneasy, and left their hives from disquictude.—Ep.]

Wintered Without Loss.—I packed 41 colonies and they are now all living, and nearly all appear to be in good condition. My bees are flying to-day. Many bee-keepers in this country have lost heavily, and are much disheartened. I hope to be able to make a good showing when I report again, say about May I.

Produced Mich. March 9 1881. Buchanan, Mich., March 9, 1881.

# CONVENTION

## Champlain Valley, Vt., Convention.

mg at Brandon, Vt., on Jan. 20, 21, 1881.
Pres. Crane in the chair. Col. H. H. Merritt gave an address of welcome, to which Pres. Crane replied, stating the object of the meeting and giving a brief narration of the ancient history of the honey bee, and of its improved management in the present age.

Mr. A. E. Manum said success depended on the man and circumstances. The bee-keeper should be a person of even temperament—not casily excited—should be somewhat acquainted with botany; and recommended small section boxes, to hold not more than 21bs. Everything should be kept ready and in order. He gave octivated and in order. He gave octivate a first statement of the surface of the statement of the statement of the surface of the surface of Meeting. April 2–8. W. Jowa, at Corning, lowa.

16–C This Association held its winter meet-

tion boxes, to hold not more than 21bs. Everything should be kept ready and in order. He gave estimate of produce in a good season with Italian bees, and also a poor season like the past.

Mr. O. C. Wait, of Georgia, said that experience had shown that bee-keeping was no mystery or slight of hand, but a clear, plain, practical science. Beekeepers were an intelligent, enterprising class of men; men of progress. No keepers were an intelligent, enterprising class of men; men of progress. No intelligent man would destroy his bees. After some discussion Mr. Manum exhibited some of his honey boxes, and explained their uses and advantages.

Bees were advantageous in the orchard, and to the buckwheat crop, as he had entisfactorily demonstrated. Some

had satisfactorily demonstrated. Some doubts had been expressed to the value of the red clover blossom on account of the inability of the bee to reach the nectary; Italians have the advantage over black bees, because they are provided with greater length of probosis.
Pres. Crane said he had noticed bees

working in red clover early and late in the season; bees will not work where

the season; bees win not work where they get no honey.

In the evening, after a few prelimi-naries, Mr. E. A. Hasseltine read a sen-sible and witty poem on "Prospects and Retrospects," which was well re-

and Retrospects, which was wen re-ceived by the andience. The talk on Sweets, by Prof. Seely, was a learned dissertation on the chemwas a tearned dissertation on the chemical properties and qualities of the various kinds of sweets that are offered in our markets. He exhibited over 20 different kinds of sugar; spoke of the various substances from which sugar was extracted, as trees, plants, roots and fruits; some specimens would solid and fruits; some specimens would solidify sooner than others; sugar from cane, corn, beets and maple, were all of the

same chemical formation. same obemical formation.

J. E. Crane spoke on the Individuality of Bees; there was a marked difference in the character of colonies, some were industrious, others not so; some prefer some kinds of flowers, others reject them; Italians dislike buckwheat, while black bees work well on it. Every colony has some popular character. He colony has some peculiar character. He cotony has some peculiar character. He showed several samples of honey from different flowers, and explained their various qualities, and also exhibited specimens of best from the Holy Land.

Dr. F. Bond said that the Creator had

Dr. F. Bond said that the Creator had placed the sweets in flowers to attract the bee, to carry out nature's laws, by carrying the fertilizing pollen to the unfertile flower, and thus showing a wise and benificent Providence.

On Friday, Jan. 21, after some preliminary business, the following were elected officers for the ensuing year: President, J. E. Crane; Vice-Presidents, H. L. Itonard, E. P. Wolcott, E. A. Hasseltine; Secretery and Treasurer, Hon. T. Brookins.

Mr. O. C. Wait spoke of the bad condition he found honey in the Boston market, and of the manner of awarding premiums at fairs.

ing premiums at fairs.
Mr. Manum remarked that it was important to have good queens, he advised all to raise their own; old queens were best to rear queens from, say 2 years old or more; it is best to rear queens in warm weather, when honey is plenty.

The question "how to prevent bees from dwindling" Mr. Leonard answered thus: In this case as in all other ills to which bee-keepers are heir to, keep the colony strong and healthy. Mr. Leonard read an essay on "Bee-culture for Women" giving instances of marked

success. He said women in Vermont were as capable and had as good facilities as in any part of the country, and would succeed as well, if attended to.

Adjourned to meet at Bristol, Vt., May next. T. BROOKINS, Sec. in May next.

### Local Convention Directory.

The In order to have this Table complete, Secreta-ries are requested to forward full particulars of time and place of future meetings.—ED.

#### CLUBBING LIST.

We supply the Weekly American Ree Journal and any of the following periodicals, for 1881, at the prices quoted in the last column of figures. The first column gives the regular price of both :

For Semi-monthly Bee Journal, \$1.00 less. For Monthly Bee Journal, \$1.50 less.

## Honey and Beeswax Market.

BUYERS' QUOTATIONS.

CHICAGO.

HIONEY.—The market is plentifully supplied with honey, and sales are slow at weak, easy prices. Quotable at 18@20c. for strictly choice white could in 1 and 2 lb, boxes; at 140-46c. for fair to good in large packages, and at 10@12c. for common dark-colored and broken lots.—Chicago Times.

BEESWAX.—Choice yellow, 20@24c; dark, 15@17.

NEW YORK.

HONEY.—Best white comb honey, small neat packages, 17@18c.; fair do., 15@16c.; dark do., 12@15; lairee boxes sell for about 2c. ninder above. White extracted, 9@10c.; dark, 7@8c.; southern strained, 80@83c.

BEESWAX.—Prime quality, 20@23c.

CINCINNATI.

HONEY.—The market for extracted clover honey very good, and in demand at llc. for the best, and able, for baswood and dark honey. Comb honey of slow sale at lcc. for the best.

BEESWAX—ISG24C.

C. F. MUTH.

SAN FRANCISCO.

HONEY.—Extracted is in large supply for the season, and purchasers for round lots difficult to find, except at extremely low prices. We quote white comb, 126,15c; dark to good, 106,11c. Extracted, choice to extra white, 660,15c; dark and candied, follows.

BEESWAX-216224c., as to color. STEARNS & SMITH, 423 Front Street. San Francisco, Cal., March 4, 1881.

## SPECIAL NOTICES.

© Constitutions and By-Laws for local Associations \$2 per 100. The name of the Association printed in the blanks for 50 cents extra.

What is the meaning of 'Dec. St' after my name on the direction-label of my paper?" This question has been asked by several, and to save answering each one, let us here say: It means that you have paid for the full year, or until "Dec. 31, 1881." "June 81" means that the first half of the year is paid for, up to "July 1st." Any other month, the same.

We will send sample copies to any who feel disposed to make up clubs for 1881. There are persons keeping bees in every neighborhood who would be benefitted by reading the JOURNAL, and by using a little of the personal influence possessed by almost every one. a club can be gotten up in every neighborhood in America. Farmers have had large crops, high prices, and a good demand for all the products of the farm, therefore can well afford to add the BEE JOURNAL to their list of papers for 1881.

as the new one.

to We have prepared Ribbon Badges for bee-keepers, on which are printed a large bee in gold. Price 10 cents each, or \$8.00 per hundred.

The Volume of the Bee Jour-NAL for 1880, bound in stiff paper covers, will be sent by mail, for \$1.50.

Notices and advertisements intended for the Weekly BEE JOURNAL must reach this office by Friday of the

\*\*Instead of sending silver money in letters, procure 1, 2 or 3 cent stamps. We can use them, and it is safer to send use them. such than silver.

Ladies who Appreciate Elegance and purity are using Parker's Itair Balsam. It is the best article sold for restoring gray hair to its original color and beauty.

The date following the name on wrapper label of this paper indicates the time to which you have paid. In making remittances, always send by postal order, registered letter, or by draft on Chicago or New York. Drafts on other cities, and local checks, are not taken by the banks in this city except at a discount of 25% to my evenes of at a discount of 25c., to pay expense of collecting them.

PREMIUMS.—For a club of 2, weekly we will give a copy of "Bee-Culture;" for a club of 5, weekly, we will give a copy of "Cook's Manual," bound in cloth; for a club of 6, we give a copy of the Journal for a year free. Do not forget that it will pay to devote a few hours to the Bee Journal.

Sample copies of the Weekly BEE JOURNAL will be sent free to any names that may be sent in. Any one intending to get up a club can have sample copies sent to the persons they desire to interview, by sending the names to this office.

Any one desiring to get a copy of the Constitution and By-Laws of the National Society, can do so by sending a stamp to this office to pay postage. It they desire to become members, a fee of \$1.00 should accompany it, and the name will be duly recorded. This notice is given at the request of the Executive Committee.

It would save us much trouble, if all would be particular to give their P.O. address and name, when writing to this office. We have several letters (some inclosing money) that have no name. Many others having no Postoffice, County or State. Also, if you live near one postoffice and get your mail at another, be sure to give the address we have on our list. dress we have on our list.

於 At the Chicago meeting of the National Society we were requested to get photographs of the leading apiarists, to photographs of the leading apparists, to sell to those who wanted them. We can now supply the following at 25 cents each: Dzierzon, the Baron of Ber-lepsch, and Langstroth. The likeness of Mr. Langstroth we have copied, is one furnished by his daughter, who says "it is the only one ever taken when he was in good health and spirits." We are glad to be able to secure one of such a satisfactory nature.

We have tilled orders for quite a number of Binders for the Weekly BEE JOURNAL. We put the price low, 30 per cent. less than any one else could afford to sell them, for we get them by the quantity at wholesale and sell them at just enough to cover the cost and postage, the latter being 21 to 23 cents, on each. We do this to induce as many The question "how to prevent bees from dwindling" Mr. Leonard answered thus: In this case as in all other ills to which bee-keepers are heir to, keep the colony strong and healthy. Mr. Leonard read an essay on "Bee-culture for Women," giving instances of marked "HUNDREDS OF MEN, WOMEN AND CHILDREN OF MEN, WOMEN AND C

## Books for Bee-Keepers.

Cook's Manual of the Aplary.—Entirely rewritten, creatly enlarged and elegantly illustrated, and is fully up with the times on every conceivable subject that interests the apiarist. It is not only instructive, but intensely interesting and thoroughly practical. The book is a masterly production, and one that no bee-keeper, however limited his means, can afterd to do without. Cloth, \$1.25; paper covers, \$1.00, postpaid. For dozen, by express, cloth, \$12; paper, \$2.50.

Anthby's New Ree-Keeping, by L.C. Root.— The author has treated the subject of fee-keeping in a manner that cannot full to interest all. Its style is plain and foreible, making all its readers sensible is plain and to the author is really the master of the subject. Price, \$1.50.

Novice's A B Cof Bee-Culture, by A. I. Root, This embraces "everything pertaining to the care of the honey-bee," and is valuable to beginners and those more advanced. Cloth, \$1, 25; paper, \$1,00.

King's Bee-Keepers' Text-Book, by A. J King, "This edition is revised and brought down to the present time. Cloth, \$1.00; paper, 75c.

Laugstroth on the Hive and Honey Bee. This is a standard scientific work. Price, \$2.00.

Hiessed Bees, by John Allen.—A romance of bee-keeping tuli of practical information and con-tagions enthusiasm. Cloth, \$1.00.

Hee-Culture; or Successful Management of the Apiary, by Thomas G. Newman,—This pamphlet embraces the following subjects: The Location of the Apiary—Honey Plants—Queen Rearing—Feeding—Swirming—Dividing—Transfering—Indianizing—Introducing Queens—Extracting—Quieting and Handlung Bees—The Newest Method of Preparing Honey for Market, etc. It is published in Equilibria of German. Price for either edition, 40 cents, postpaid, or \$3.00 per dozen.

Food Adulteration; What we eat and should not eat. This book should be in every family, where it ought to create a sentiment against the adulteration of food products, and demand a law to protect consumers against the many health-destroying adulterations offered as food. 200 pages. Paper, 50c.

The Dzierzon Theory; presents the funda-mental principles of bee-culture, and firmishes a condensed statement of the facts and arguments by which they are demonstrated. Price, 15 cents.

which they are demonstrated. Price, 15 cents.

Honey, as Food and Medicline, by Thomas G.
Newman.—This is a pamphlet of 24 pages, discoursing upon the Ancient History of Bees and Honey the nature, quality, sources, and preparation of Honey for the Market; Honey as an article of food, giving recipes for making Honey Cukes, Cookies, Puddings, Foam, Wines, Ac.; and Honey as Medicine, followed by many useful Becipes. It is intended for consumers, and should be scuttered by thousands all over the country, and thus assist in creating a demand for honey. Published in English and German. Price for either edition, 6c.; per dozen, 50c.

Wintering Bees.—This pamphlet contains all the Prize Essays on this important subject, that were read before the Centennial Bee-Keepers' Associa-tion. The Prize—ES' in gold—was awarded to Prof. Cook's Essay, which is given in full. Price, 10c.

Hees and their Management. This pamphlet was issued by the Italian Bee Company, and has had a large circulation. The price has been reduced from 20 cents to 10 cents.

The Hive I Use—Being a description of the hive used by G. M. Dooluttle. Price, 5c.

Kendail's Horse Book—No hook can be more useful to horse owners. It has 35 engravings, illustrating positions of sick hoses, and treats all diseases in a plain and comprehensive manner. It has a large number of good recipes, a table of doses, and much other valuable horse information. Paper, 25c.

Chicken Cholern, by A. J. Hill,—A treatise on its cause, symptoms and cure. Price, 25c.

Moore's Universal Assistant contains information on every conceivable subject, as well as receipts for almost everything that could be desired. We doubt if any one could be induced to do without it, after having spent a few hours in looking it through. It contains 480 pages, and 500 engravings. Cloth, \$2.50.

Rnpp's Easy Calculator.—These are handy tables for all kinds of merchandise and interest. It is really a lightning calculator, nicely bound, with slate and pocket for papers. In cloth, \$1.00; Morocco, \$1.50. Cheup edition, without slate, 50c.

For the American Bee Journal

### What is the Royal Jelly?

C. J. ROBINSON.

I propose, by permission, to discuss in the columns of the BEE JOURNAL the hitherto puzzling problem: "What is royal jelly, that substance known to produce the transformation of worker larvæto queens?" Profound scientists of Europe and this country have delved into the secrets of the grand problem, but none of them have handed down a satisfactory solution. Yet, it does not seem rational that the question is so obstruse as to forever remain past finding out what the so-called royal jelly consists of; the source from which it is derived; its definite action on larvæ and whether it is administered by the workers as a nourshing aliment to larvæ in royal cells, or for the purpose of impregnating the larvæ (as pistilliferous in royal cells, or for the purpose of impregnating the larvæ (as pistilliferous flowers are impregnated with pollen) and thus develop a female bee fully qualified to reproduce males. The settled doctrine of writers on bee-matters is that it is chiefly due to the excess of food served to the larva by the workers that produces the transformation from that produces the transformation from worker to queen. Still no writer has ventured to assert that such is a demonstrated fact. The late Baron of Berlepsch, the able expounder of the Dzierzon Theory, and the most scientific and practical apicultural writer and experienced apiarist in all Europe, wrote thus:

"Every hypothesis, however, yet sub-mitted from any quarter, rest chiefly upon the assumption that the develop-ment (of fertile workers and queens) has by some means been over lated for a brief period, and as the result affects the sexual organs more especially, the quantity and quality of the pecially, the quantity and quarty of the food administered has been looked to as

individual female bees are very likely individual temale bees are very likely to be reproduced imperfectly developed in all the degrees between a rudimentary fertile worker up to a perfect queen. Furthermore, were it true that development depends on quantity of food or the over-stimulating caused by high feeding the matter would be able high feeding, the workers would be able to supply themselves with queens at all times; when on the contrary it is well known that workers cannot always perthown that workers cannot always per-fect queens when furnished with every-thing necessary for that purpose except the impregnating principle—semen. A full knowledge of the reproduction

A full knowledge of the reproduction of the honey bee is of great importance, and at the very foundation of the science of bee culture and of great value to those who intend to breed the superior races of bees, especially the princi-ples of hybridizing so as to prevent their deterioration and improve the breeds. And it is of great moment to the science of entomology to determine whether insects are produced by par-

EGGS AND LARVA.

thenogenesis, as is believed, or by se-

thenogenesis, as is believed, or by semen received by the male progenitors. As for myself, I have conclusive evidence that such queens as are reproduced by furnishing a colony of black bees with eggs laid by an Italian queen, is in some degree hybridized.

All of the points in the "Dzierzon Theory" have been demonstrated except his theory of the reproduction of bees, particularly drones and queens. It seems that he was sorely puzzled in his profound research to comprehend the laws involved in the strange phenomena—virgin queens reproducing male ena—virgin queens reproducing male bees—and to dispose of the (to him) inbees—and to dispose of the (to him) in-explicable point in his colossal theory, he jumped at a conclusion which was based upon the hypothetical doctrine advanced by Professors Von Seibold, Lenekart, and Dr. Donhoff, the fathers of the theory catled "Parthenogenesis," that is procreating without male sperm. It was during the period that Dr. Dzier-zon was making public his theory that Mr. Elihu Kirby, of Henrietta, N. Y., attempted to make known the result of his long-time and attentive research into the principles of reproduction of

rience, and enthusiastic in the cause of progressive bee-culture. Not until 1861 was there published or circulated in this country a periodical devoted to bee affairs and scarcely no attention was given to scientific bee-culture at that time. Mr. K. communicated to the American Bee Journal at different times just after its advent, the discoveries be had after its advent, the discoveries he had made relative to the reproduction of bees, but not much attention was given it further than a brief notice by the editor, the lamented Samuel Wagner, who, like the great Dzierzon, seemed not to comprehend the evolution of the reproduction of insects.

During the period of 1859-63, Mr. Kirby was in failing health, and when in the summer of 1863, he was about to bid adieu to his long-cherished theme and go from the altar of home on earth to a heavenly intentions he heavenly. to a heavenly inheritance, he besought me to further his designs and he committed to my charge his new theory of the reproduction of drones and female bees. The result of the case thus con-signed to me is as follows, conclusions that I have come to derived from careful observations for many seasons, viz.,

ful observations for many seasons, viz., ridelicet.

To produce drones the workers fecundate the worker lave in royal cells with drone's semen, which gives the elements of queens. The workers supply the said larva with animal secretion, water, bee-bread and honey, until it secretes sufficient material for a queen, and when the larva arrives at maturity it is then metamorphosed to an egg substance, from thence it passes to a substance, from thence it passes to a chrysalis state, and in the pupa-state her ovary is formed and impregnated with semen retained in the larva state imparting the elements of life. She then leaves her cell and is prepared to her eggs that we draw draws out. She then leaves her cell and is prepared to lay eggs that produce drones only, without further fecundation, and when the drones are matured from their natural genital propensities deposit their semen in the queen's spermatheca to enable her to fecundate her full grown eggs to produce workers and also deeggs to produce workers, and also de-posit semen where the workers can obtain it in the abscence of the drones, to perfect queens, and for storing it in their combs, where it retains its vitality at least from the time that the drones are expelled until they are reproduced the following season. It is ascertained the following season. It is ascertained that the drones and queens can be hybridized by their drone progenitors in the embryo state, which is conclusive evidence of their being fecundated with drones' semen.

To produce workers the drones de-To produce workers the drones deposit their sperm in the queen's spermatheca while on the wing (and on top, elasping the drone's back to herself) and from thence she fecundates full grown eggs, as they pass the mouth of her spermatheca on the way out of her oxidizet and by the combining of the oviduct, and by the combining of the elements of the drone and worker in one, by which the worker is produced. Thus, there can be no logical reasoning in saying that the workers are produced by semen, and the drones and queens are produced without semen.

To produce queens the worker fecun-As making putility is theory that to produce queens the worker lecture teed for a brief period, and as the result affects the sexual organs more established the sexual organs more established to make known the result of attempted to make known the result of the different research into the principles of reproduction of reproduction of reproduction of reproduction of combined in one, in the larval state; it the different races of honey bees. He was a scientific apiarist of long experial for perfect queens, and when the

larva arrives at maturity it is transformed to an egg-form, and then to a chrysalis, and in that state her embryo ovary is formed and impregnates in the upper points or sacks of her ovary, and contains the elements of myriads of contains the elements of myriads of drone egg germs before leaving her cell, and her physiology is changed in her transition from the chrysalis state to a perfect queen, and is qualified before leaving her cell to lay eggs that will produce drones only. To be fully qualified to produce workers she must receive a deposit of semen from the drone in her spermatheea. If once filled with semen it is efficacious through life, and qualifies her to fecundate the fified with semen it is efficacious through life, and qualifies her to fecundate the full grown drone eggs as they pass the mouth of her spermatheca, and causes them to produce workers, and to lay all the eggs, both male and female and workers, that the colony may require. It is ascertained that the embryo drone, workers and queen can each be hybrid-ized in the overy egg or layer that ized in the ovary, egg or larva state, which is communicated to the whole production. I think the evidence con-elusive in the reproduction of the queen. The fertile workers are produced by the workers taking the drone's semen into their stomachs, and from thence it is transmitted to their embryo ovary, and transmitted to their embryo ovary, and fecundates it, which gives the elements of life to the progeny, and qualifies them to lay eggs which produce drones only, unless the eggs are further fecundated by being brought into contact with semen. It appears that the young queen's ovary on leaving her cell, and the ovary of the fertile worker when fermulated we identically the appears to the production. cundated, are identical in the production of drone eggs. Thefore, the evidence is that semen is the agent in both cases. I wish to call attention particularly to the following points: 1st. The em-

to the following points: 1st. The embryo ovary of young queens must be fructified before she leaves her cell with drone's semen, which gives the elements of life to her drone progeny, and forms the basis for the whole progeny of bees. To produce the 3 seves of bees there are 3 distinct fecundations. 1st. The embryo ovary of the pupa queen to produce the drones. 2d. The full grown egg to produce the workers. 3d. grown egg to produce the workers. 3d. The worker larva is fecundated by the workers with semen, given off by the drones to produce the queens. And all in the larval state the ysecrete sufficient material to perfect in their transition either drones, workers or queens, and they creb can be hybridized in the and they each can be hybridized in the

embryo state.

2d. In the reproduction of bees there are 2 distinct egg forms: 1st. The eggs that produce the larva. 2d. The larva when it arrives at maturity is transformed to an egg substance, of which it forms the chrysalis that produces the perfect bees and their sexes.

. It requires 3 states of existence to 3d. It requires 3 states of existence to perfect the organism of bees. 1st. The larva. 2d. The chrysalis. 3d. The perfect bee. The queen first deposits her eggs in the proper cells or utricals in which the larva is hatched and supplied by the workers with animal secretion and food until their transition to an egg

and food until their transition to an egg substance or chrysalis.

I will propose the following question for consideration: What is it that is found in the royal jelly that is possessed of such impregnating powers as to cause the ovaries of the workers to produce drone eggs?

Riehford, N. Y., March 14, 1881.

For the American Ree Journal,

## Putting Wires into Comb Foundation.

J. G. WIHITEN.

Mr. John F. Cowan, in his article on The Practical use of Foundation," published in the Bee Journal of March 9, says: "It has been practically demonstrated to my satisfaction that these results can only be obtained by Mr. Given's method of introducing the wires, and if by a happy combination the Dunham foundation could be made and wired by the Given or a similar process, the foundation controversy would be virtually ended."

I would like to say to Mr. Cowan and

others who may be interested, that last season I hived about 40 full sized natuseason I invertation to turn sized natural colonies, on Dunham foundation, in Quinby frames, prepared in the following manner: The frame is wired by sewing in 2 horizontal wires, spaced off see that there will be 3 equal spaces from the top bar down. I use a triangular top-bar and fasten the foundation by pressing it down to the bar with the thumb and then running a stream of melted wax and rosin over it. Then by running a wheel, made of a cent, over the wire I imbed the wire into the foundation; this also forms a groove in the foundation in which I run a stream of melted wax which covers the wire, and when drawn out will be perfect and will neither sag nor break out by ex-tracting. There should be a good half tracting. There should be a good half inch of space by tween the foundation and bottom bar, as it will settle enough to bulge the comb if left full length. To give it a thorough trial I hived 2 heavy natural colonies in one hive with the mercury at 90 in the shade and basswood honey coming in very fast, and when drawn out every comb was perfect. By bending a spoon so that it will pour a small stream and with a little practice, you will find it a short task to fasten the foundation in the frames. Genoa, N. Y., March 14, 1881.

For the American Bee Journal.

### Importing Bees from Italy.

CHAS. DADANT.

Mr. A. Salisbury, under the above heading, says that "It is no longer a question: the Italian bee of Italy is not a distinct race.... Later investigation proyes the fact that there are black bees in Italy, as anywhere else, even in the vicinity of Rome itself."

Mr. Jones, at the Convention in Cincinnal last fall asserted that he had

Mr. Jones, at the Convention in Cincinnati last fall, asserted that he had seen black bees at several places in Italy, even in the vicinity of Rome. All my inquiries, as well as the reports of prominent and disinterested beekeepers of Italy, such as Mr. Mona and Dr. Dubini, prove that there are no hybrid bees in Italy, and, of course, no black beas

Will Mr. Jones tell us in which apiaries he saw black bees? Of course, by black bees we understand entire colonies of black bees. Then, he saw also colonies of hybrid bees, for the mixing could not be prevented. But if Mr. Jones saw only a tew black, or seemingly black bees, in a colony, this circumstance, caused either by the dark contents of their stomachs, or by some other accidental cause, we cannot infer from it that there are black or impure bees in Italy that Mr. Jones will answer this question.

question.

Mr. Jones adds that, in his opinion, the Italian bees were descended from the bees of Holy Land, or those on the Island of Cyprus. Such an opinion raises the question: Are the yellow bees from Cyprus, from Syria, or from Italy, the original bees; or the black bees, of more northern climates, the original bees the yellow galor being only an inbees, the yellow color being only an improvement?

According to the law of natural selection, the yellow bees of these three countries are about similar, because the three countries enjoy a mild climate. The idea of Mr. Jones' that the Italian bees descended from the brees of Cyprus or of Syria, cannot be sustained, for it leads to the idea of large importations of bees from these countries, into Italy, at a time when the means of transportation were few, long and difficult.

these bees into Italy would have been unable to effect the smallest change in mable to effect the smallest change in the race then existing; for by our intro-duction of Italian bees we have expe-rienced how hard it is to overcome the returning to the type which is prevalent in a country. Besides, although we have had too little time to study the habits of the Cyprian bees, having re-ceived our queens last summer only, we have noticed that, while they resemble in color the Italian, their habits are not the same. For instance, the Cyprian bees do not cling to the combs as persistently as do the Italians, and resemsistently as do the fundins, and resemble more the blacks in this respect; the Cyprian queens, like the common queens, are more easily frightened, and more difficult to find, than the Italian

As to their other qualities we are unable to say anything. It will take a few seasons to test them thoroughly. It is, therefore, desirable to see them tested by a great number of bee-keepers in comparison with Italian bees.

I read in the Italian bee paper, L'Apicoltore, for January, just received, that the Central Society of Italian Bee-Keepers will have an exhibition on the first of May, to which the bee-keepers are invited to send bees from every part of the country (probably to answer the assertion of Mr. Jones, that there are black bees in Italy), in order to compare the varieties which can exist on the entire peninsula. The report of the commission of this society will thus put an end to the discussions between those who contend that there are black bees in Italy, and those who say that the Italian bees are all pure. Yet, it is well to remember here, that in Italy, as well as in Germany, they count but two yellow rings; for they do not count as a ring the first segment, to which the thois attached

rax is attached. Hamilton, Ill., Feb. 5, 1881.

#### Bees and Grapes.

REV. M. MAHIN, D. D.

I notice that the question whether I notice that the question whether bees destroy sound grapes is again being discussed. I have been a beekeeper for II years and during most of that time have raised grapes enough for family use, and I have given considerable time and attention to the question under discussion. All my observations go to show that bees do not pumeture sound grapes. I have seen puncture sound grapes. I have seen them sucking the juice from grapes that had been broken by birds, and have that had been broken by birds, and have picked off the broken grape, and watched the result. The bees would run about over the bunch hunting for an opening, and finally abandon the scarch. Last season a great many grapes were destroyed or injured in this part of the country, and I gave the matter special attention. Many of the grapes cracked more or less from the effects of rains following dry weather, erects of rains following dry Weather, and many more were broken more or less by birds. As forage was scarce the bees worked industriously on these broken grapes until they were all gone. But on all the bunches there were some grapes that were not broken, and these grapes that were not broken, and these remained on the vines until late in the season. After the juice had been sucked from all the broken skins I saw the bees for many days vainly searching of the bees for many axy varing searching for openings from which they might obtain the supplies they had been accustomed to draw from the broken fruit. These sound grapes remained on the vines, in some cases, for weeks after the bees had ceased to get anything from the broken. thing from the broken ones. Now it is plain that the juice of these very ripe grapes would have been quite as acceptable to them as that from the ones they are accused of having punctured and destroyed. And to my mind it is clear that if they had punctured and destroyed as many as they are accused of doing, they would not have become suddenly reformed as the grapes became sweeter and more delicious. L will not affirm that the bees cannot puncture the skin of a grape, but I do affirm that as tar as my very careful observation en-ables me to judge, they do not. And if I am correct in this the injury done

The introduction of a few colonies of to the grapes is very small. The injured popinion, on page 59, was exactly our ex-

wasps, hornets, &c., do little injury to grapes. The mischief results mostly from the cracking of the skin, by a very few days, even, of wet weather after it has been dry for some time. The skin of the grapes becomes so full that a jar of the grapes becomes so full that a jar from the wind or from the alighting of a bird on the bunch, will cause them to crack, and then, if there is a dearth of honey, they are sure to be sucked dry by the bees, with more or less help from yellow jackets, hornets, and wasps. It is possible that in some cases the skins are cut by wasps &c. but I skins are cut by wasps. &c., but I think the cases are exceptional.

#### The Use of Separators for Box Honey

GREINER BROTHERS.

In starting an apiary it is of great importance to adopt a hive that will prove satisfactory to the manager, in all its features, for the present as well as for the future. It is not an easy matter af-ter an apiary has been started and hives and appliances have accumulated, to change the sizes or dimensions of such, if they should not be satisfactory. In the different manifestations of the hive we find that it is necessary to have brood frames and sections interchangeable, in fact, it is still more convenient to have all the different parts of the hives as uniform as mechanical workmyes as uniform as inechanical work-manship can produce them, so that frames, honey-boards, division-boards, covers, sections, mats, &c., may be picked up anywhere and adjusted to any hive desired.

The use of separators is another fea-

the use of separators is another rea-ture of this kind; if once adopted and the bees arranged accordingly, it may cause considerable trouble to remodel a lot of appliances, especially if sepa-rators of any perceptible thickness are used.

In the BeelJournal for Feb. 2, Mr. Heddon gives some very good hints on hive and section making, "but we can not endorse all his points, and in this article we refer in particular to his closing sentence.

It seems strange to us that Mr. Heddon pronounces separators "nuisances," whilst other prominent bee-keepers, and we believe the majority, use them and advocate their use. It must certainly be a query to young beginners, who seek information amongst the contributors of the Journal, to encounter such square contradictions, perience is about as follows: Our ex-

The 2 first years of our experience in bee-keeping found as equipped with bee-Reeping found is equipped with open surplus cases, we mean by surplus cases the adjustible half-story, with the proper number of frames con-taining sections. The seasons were good and the crops abundant, but the shape of a good share of our honey was anything but desirable; it was not uniform in thickness nor even; some being thick on one end and thin on the other, some were missed entirely, whilst the adjoining one bulged out to take up the space; in short, the variations were

To glass and crate this honey for mar to glass and crate this lonely for market cost us considerable trouble and we concluded to try separators. The 25 cases we had prepared and used the next season at our honey apixty proved to be separators. to be a success; the honey was "just splendid;" the sections in shape, thek-ness and weight were as near perfect as could be desired, and we decided at once to produce honey in no other way. However, we were not entirely satisfied; we knew separators were objected to by some bee-keepers on account of a smaller yield. Mr. Heddon says, on page 33 of the JOURNAL, "These separators of the JOURNAL, "These separators of the JOURNAL,"

grapes would spoil in a few days if the bees were not to touch them.

As far as 1 have been able to observe cost and trouble of manipulating to be cost and trouble of manipulating to be objectionable. We admit separators are an expense, but they need not be very costly. We use basswood, costing as less than a cent each, and even at twice that cost, would it not be economy then to expend a comparative small amount if we can thereby produce honey in much more attractive shape Besides we claim separators lessen the trouble of manipulating instead of increasing it. The reason we use wood is because it is cheaper than metal and we believe better adapted, on account of its being the most natural material

of its being the most natural material for bee-habitations.

Since we introduced separators the percentage of unfinished honey is greatly reduced. At the end of the honey season we formerly found open cases almost filled with comb and honey and not one single finished section among them. This is not so much the case since we use separators; when the flow of honey begins to diminish, we have noticed our bees to be at work we have noticed our bees to be at work in a portion of the sections, whilst the remainder would not be occupied at all; we have also taken off cases at the end of a honey flow, which were entirely empty, except 2 or 3 sections, and these were finished and marketable. To be sure these are extremes, but it shows the benefit of separators

It might appear from the last part of this article, that we apply surplus cases regardless of the working capacity of our colonies. Circumstances may sometimes compel us to do so, but we aim to give our bees no more surplus room than they can occupy. Naples, N. Y., March 6, 1881.

### Texas for Bees and Honey.

DR. J. E. LAY.

I write to answer several communica-tions in regard to the adaptability of our great State to bee-keeping, and as apiculture is engrossing the minds of many of the most energetic, progressive and scientific men of our land, I recogopinion. As our great State is so varied in climate and flora, I will state that my remarks have reference to my own my remarks have reference to my own section of perhaps a radius of 100 miles. I have lived in Texas since 1850. I passed my boyhood days on her beautiful prairies, amid her thousands of flowers of every hue, treighting our incomparable sea breeze with more than Arcadian sweetness, silence banished from her woodland slopes by the joyous carol of beautiful song birds. Ever delighting in the marvelons beanties of nature, how could I fail to love so beauteous a sun-lit home? Yes, and as a grown up boy I love it still. Greek nor Roman, not even Wm. Tell, loved his country better than I, therefore my bee-keeping friends will pardon me if I seem to color a little too strongly. Our State is being filled with energetic farmers who are reaping rich harvests farmers who are reaping rich harvests from the yirgin soil, for nearly all kinds of seeds that are sown spring forth un-der the genial rays of the sun to 60 and an hundred fold.

Reasoning by analogy I opine that bee-keeping will result in like manner. Apiculture is in its nascent form here, Apiculture is in its assemt form here, but the sun of science begins to warm its quickening form. I have studied the best works on apiculture, but have not given it a thorough practical test yet; I purpose doing so this season. There are but few bees in our country, all blacks event by little arises. all blacks except my little apiary of 7 colonies, which consists of hybrids and blacks. I intend to Italianize in March, for they indeed possess many advantages over the blacks.

d and clear page 33 of the JOURNAL, "These separators cost me too great a portion of my surplus crop."

To satisfy ourselves on this point we came ll not cases, rigged as the first 25, with separators, which we scattered in our different at as on en-danger and anount of honey stored, and the editor's labeled amount of honey stored, and the editor's

ferent is the climate over which our vast brotherhood reaches! Our honey ferent is the climate over which our vast brotherhood reaches! Our honey plants reach nearly through the entire year, yielding as good nectar as ever tickled the palate of man. In fact the harvest for bees is almost endless, better, of course, some months. The marginal plants are the course, some months. harvest for bees is almost endless, better, of course, some months. The market for honey has never been developed; a few old "gums" to "rob" for "big meeting" or for some extraordinary visitor is about all ever obtained. "Bees do no good here these days, the moth destroy them," say the "old settlers." The moth skulks away in the light of seigntiffactors, beginning and its depredascientific bee-keeping and its depredations are nil.

To be successful all should study the science, read good books on the subject learn by close practical observation, read the periodicals of our wide awake bee-men, among which there is none better than the AMERICAN BEE JOURwill succeed even in the "sunlit clime" of Texas. Without these, all will just of Texas. Without as surely retrograde.

Hallettsville, Texas.

For the American Bee Journal

## Alsike Clover as a Honey Plant.

L. JAMES.

Much has been written for the Jour-NAL about the value of this variety of clover for its yield of honey and hay. Such has not been my experience with it, sown on 19 acres of land, and extending over 11 years. In 1869 I bought some 38 pounds of the seed of Mr. Thomas, of Canada. The cost to me. of the seed, duty and express charges, of the seed, dity and express charges, was \$18. Having 9 acres of ground planted with apple trees that had been bearing for some time, and wishing to seed it down to grass I had the ground well prepared for the reception of the seed, and a good rain fell just after it was brushed in; it came up nicely, and as there was favorable rains all through as there was tavorable rains all through the summer it grew inley. The follow-ing season it grew in length of stem and quantity of bloom far beyond my ex-pectation, and when in its full bloom it was a beautiful sight, resembling an ocean of blossoms, and as I looked upon it was may rely man it my calculations ocean of blossoms, and as flooked upon it, you may rely upon it my calculations of boxes of nice alsike clover honey loomed up in large proportions, but like many another calculation based upon what our bees are going to do, it was all in fancy and I was doomed to disappointment.

Day after day their flight was just in Day after day their flight was just in the opposite direction, with only here and there a bee to be seen on it. There was a body of timber 34 of a mile distant in the direction they were flying with pastures well set in white clover between this timber and the apiary, and I supposed the white clover pastures was the source of honey supply. This state of things continued for some time. and seeing a bee-man pass by that lived in the timber I inquired how his bees were getting along. He replied they were doing finely as they ought to, for he had never seen heavier honey dews. That was the secret, and soon my boxes began to show evidence of the dark staff. began to show evidence of the dark stuff being put into them, instead of alsike honey. Fortunately for me, before much of it was stored in the boxes, some heavy dashing rains washed it from the leaves and there was no more of the dew for them to gather. The al-sike and white clover were in bloom for sike and white clover were in bloom for some time after this, but for some cause the bees paid but little attention to it, and I was vexed to see the promise of a rich return for my expenditure frustrated. I took it for granted that the season was not congenial for its production of honey, as I knew the same to be the case with white clover, as it was last summer. After this at difference that the same to be the case with white clover, as it was last summer. to be the case with white clover, as it was last summer. After this at different times I sowed 2 other orchards of 5 acres each with alsike, neither of which did as well as the first piece sown, want of timely rains, &c.. being the cause, but by continuous sowing I succeeded in having them tolerably well set with it.

Receiving no percentible benefit from Receiving no perceptible benefit from

it, commensurate with its trouble and expense, I have for some time been satisfied that in central Illinois where our white clover is so abundantly further three part and ward sides. nished in our pastures and road sides, without any expense, and hardy at that, it is time and money put to a poor use.

As a hav producing plant it amounts to but little after the first season, as it becomes dwarfed in habit, and, I believe, will eventually be but little larger in growth under like circumstances than the white variety. The white than the white variety. The white clover is the honey plant for our latitude, and I presume the alsike for Sweden, from whence it came, and corresponding latitudes. After having had II years' experience with it I think it in more than the corresponding to the content of the content of the corresponding latitudes. it unworthy of attention from bee-men, either for honey or hay; at least where the hardy white clover comes spontaneously to our hands.

There is one thing I ought not to omit, in sowing this Canadian seed I introduced a kind of cockle (different from any I have seen in Penn. or Ohio) that holds its own much better than the clover, and I begin to think it will be a standing pest difficult to get rid of.
Atlanta, Ill.

Read before the N. E. Convention.

## The Supply and Queen Trade.

A. B. WEED.

This is a subject, I believe, of interest to all who are engaged in apiculture, either as bee-keepers, supply dealers or queen breeders, and is growing as the business extends.

business extends.

The supply business seems as yet to be in a crude state, and prices lack uniformity. In many cases we find needless "cutting" of prices. It may be said that this is a good thing for buyers; but I believe that the opposite is the case, for the inevitable result of unreasonably low prices is inferior goods. When prices are so lowered that there is no margin left for profit, the trade will not be supported with the enterprise which is necessary to stimulate improvements or inventions, or even to improvements or inventions, or even to put the business on a good footing. The character of the business can best be maintained if the energy of manufacturers is directed to the perfecting of goods rather than the character of of goods rather than the cheapening of of goods rather than the cheapening of them. Good tools are necessary in any pursuit, and seem to be associated with a thrifty business; in fact, the prosper-ity of a business is largely dependent upon the means at hand of carrying it on. If one tool is better than another even if the difference is slight—it is worth very much more, for the benefit worth very much more, for the benefit of the difference is felt every time that it is used. A good thing may be a source of profit, and a poor one of loss. The best is always the cheapest.

There is one respect in which the business is in a better condition than many others, and that is, that there is but very little credit given. This is an

but very little credit given. This is an advantage to both parties, for the seller loses nothing through bad debts, and the prompt buyer does not have to pay for the losses caused by the care-less or dishonest ones.

less or dishonest ones.

It is quite common among supply dealers to guarantee safe arrival of goods. This condition of sale is unnecessary, as the express receipt is sufficient, and in case of injury or loss the fact is more readily proven and damages more easily collected than could be from some dealers. It is unreasonable to expect the dealer to be responsible for goods after they have left his hands, especially when the consignee can adespecially when the consignee can adjust any difficulty more easily at his end of the line; this is the customary rule in business. When articles are sent by mail the buyer can protect himself against loss by having the article registered; but the precaution is almost unnecessary, as it is very rarely that anything is lost in the mails. Of course

anything is lost in the mails. Of course the sender is required to use necessary care in packing; with most shippers this is a point of pride.

The traffic in queens seems to be closely allied to the supply business—at least so I have found it—for as the beckeper begins to feel the need of good teach. The traffic in queens seems to be closely allied to the supply business—at least so I have found it—for as the beekeeper begins to feel the need of good tools he sees the advantage of good stock as well; and he naturally looks in the same direction for both. I believe that I express the opinion of the best queen breeders when I say that it is much more satisfactory to sell a good queen at a correspondingly good price—even if the profit is no greater in proportion—than a cheap and poor one, for the reason that a queen, wherever she included in the midd winter, also that they are wintered successfully if well packed in chaff in a cold winter; but I claim that the labor of preparing them is more than double that of cellar wintering.

I contend that the only certain way is to prepare a snitable place especially for the bees. If a cellar, have the floor cemented and see that it is dry, dark, and well ventilated. In such a place they will not consume more than half the amount of honey they would it left out "packed" in the most approved

goes, will represent the stock from which she came. And I believe, too, particutant I speak the opinion of all observing apiarists when I say that it pays institutional the stock from which is a speak to the stock from the stock fr finitely better to keep good queens than poor ones. Thus it is that good queens poor ones. Thus it is that good queens at good prices are more profitable to both parties. Some of the best apiarists have discontinued selling any queens that are not possessed of a high degree of merit, and send out only those which are thoroughly tested and found to be good. In return they receive a suitable good. In return they receive a suitable price from appreciative customers. This is notably the case in localities where honey raising is an established business, and the value of good stock is therefore understood. It is now almost universally held by apiarists that if good queens are to be obtained they must be raised under favorable conditions. It is freely admitted that to bring about these conditions requires a large outlay of time and thought, as well as money.

This especially is the case when queens are to be reared out of season.

The cost of rearing queens will decide their price, for of course they will not be sold at prices which do not pay for rearing and a reasonable profit besides. If hypers insist on having chem. for rearing and a reasonable profit besides. If buyers insist on having cheap queens, they will get them, but their value will be found to correspond with their price. The one-price rule, which is applied to queens throughout the country, has the effect of causing many year early to be sold at fair prices. country, has the effect of causing many poor ones to be sold at fair prices, which really should be killed. It has the ten-dency to discourage the rearing of very superior ones, for as a rule, a thing is no better than its price. When they no better than its price. When are all sold at a uniform price it is expected they will be nearly alike in merit, as there is no special inducement for the breeder to improve his stock. The uniformity of price probably originated in the supposition that all queens are equally good, whereas experience proves the opposite to be true. A queen that lays even a few more eggs than another is much more valuable, for the extra number of eggs will be for the extra infiniter of eggs will be multiplied by the number of days that she is kept. This difference alone, so often repeated, will in time amount to more than the price of the queen. A poor queen is kept at a corresponding loss, although both may have sold at the capie, price. There are such things as same price. There are such things as plus and minus outside of algebra. The buying of queens at present has some resemblance to a lottery. They should be graded—at least so far as this is possible, and wiced accordingly. sible-and priced accordingly.

Combinations for the maintenance of artificial prices are impracticable and undesirable. I would only submit that prices be based upon cost of production and a reasonable profit.

Detroit, Mich.

For the American Bee Journal.

## Who is to Blame for the Losses?

C. H. DIBBERN.

Already the reports of fearful losses are coming in thick and fast. Every severe winter the story is the same. Now the question arises, are these losses of bees inevitable every cold winter? If so then our business as bee-keepers

The other our business as bee-keepers is still a mere matter of luck.

During the last few years of mild winters the out-door wintering men have had things about their own way in our bee-papers. Now, are these papers not a little to blame for admitting the beautiful and the columns giving head at the columns giving head at pers not a little to blame for admitting articles to their columns giving bad advice to the inexperienced? Many have advocated the wintering on summer stands without protection or care, and persistently claim to be masters in beekeeping. I am perfectly willing to admit that bees can be wintered very nicely on summer stands in a mild winter also that they are wintered success.

This being a fact they have no particular occasion for a flight. I know that the ont-door men claim that cellar-wintered bees do not breed early and are liable to "spring dwindle." I hardly know what spring dwindling is. By good spring management 1 have never failed to have my hives crowded as soon as there is anything for the bees Then what is to be gained by to do. Then what is to be gained by having the queen expend her energies and raising vast broods of bees in February to be ready to die when the blossoms come? But sometimes failure comes even in the best of cellars; but would they have fared any better out of doors? Nine times in 10 the cause can be traced to bees filling their hives from the refuse of eider mills. How to keep them from storing such stuff is one of the great problems to be solved.

It is not to be supposed that any kind of a hole under a house will do to winter bees. I have known bees to be ter bees. I have known bees to be packed away among onions, cabbage, and sour kraut. In the spring they wonder what made their bees die. Perhaps they were fastened by wire cloth so that the light could be let in and the bees could not "get out you know." That such must fail is apparent.

I do not find fault with those who pre-fer to pack in chaff and winter out of doors; I cannot see, however, that it is the best way.

It will be the "survival of the fittest" this winter, sure. The box hive men and careless bee-keepers will go out of the business. It is the golden opportunity for the bee-keeper of the future. Soon the fields will be white with the harvest, but the laborers will be few. The bees will have less competition in the fields and the honey in the market.
Milan, Ill.

[Are the papers reprehensible for giving place to candid and respectful arguments, whether based upon tenable or doubtful theories, intended to advance and simplify a science of such magnitude as the bee-keeping interest? Differences of opinion (and honest ones, too,) exist in almost all leading pursuits, and frequently, although seemingly contradicting each other, lead to successful results; again, as has been frequently demonstrated during the past winter, practices embracing all the most approved theories, have alike proved disastrous. There are so many favorable contingencies to be provided, that theories are powerless to insure success. It is interesting, as well as mystifying, to glance through our correspondence from week to week, and note the different methods of preparing bees for winter, and the disasters attending all the different styles. Nor are the cellars exempt from heavy losses, even where success has been proverbial heretofore. The truth is, the winter has been an exceptional one, and loss or success with a single or a few individuals, will neither establish nor disprove theoretical assertions; nor will it justify the "I told you so" class, because successful, in arrogating to themselves all of human wisdom.-ED.]

The North Western Wisconsin Bee-keepers Association will meet at Germania Hall, LaCrosse, Wis., on Tuesday, May 10, at 10 a. m. All interested in bee-keeping are requested to be present. L. II. PAMMEL, JR., Sec.

The next meeting of the N. W. Illinois and S. W. Wisconsin Bee-Keepers' Association, will be held at H. W. Lee's, 2 miles n.w. of Pecatonica, Winnebago county, Ills., on the 17th of May, 1881.

J. STEWART, Sec.

TOn account of unfavorable weather the convention at Monroe Centre, III., met on Feb. 8, and there being but few present, adjourned to the same place on March 29, 1881.

A. RICE, Pres.

#### THOMAS C. NEWMAN.

EDITOR AND PROPRIETOR,

CHICAGO, ILL., MAR. 23, 1881.

### Frank Benton in the Far East.

Mr. Jones sends us the annexed exto the BEE JOURNAL, for which he will accept our thanks:

Herewith I send you extract from a private letter just received from Frank Benton, dated Pointe de Galle, Ceylon, Asia, Jan. 30, 1881. The American Bee Journal has a warm corner in my heart. Right glad am I that you have taken time by the forelock, and issued a weekly. I would not have you go back to a monthly for \$25 a year, and you deserve the congratulations of every bee-keeper; that prosperity may crown your efforts is my wish. D. A. JONES.

FRIEND JONES: —\* \* \* I shall start

back with nothing but full colonies. have seen two native races of bees here, and the comb of a third; one race is stingless, but worthless; the timest little fellows, three-sixteenths of an inch long. Another race is Apis indica.
The third race I do not believe is valuable, since it is a very small bee—smaller than Apisindica. Apis dorsata is a wonderful bee, whether it can be domesticated or not. It builds in the open air, on branches, often making combs 6 feet long; and I have good authority for saying that 30 natives have each taken a load of honey from one tree. It was not until I reached Colombo that I could find out anything about *Apis dorsata*. I call it *Apis dorsata*, but do not know positively as that is its name, for no one can tell here, and I have not yet seen the bee, as it was too late when I learned where to find it, to go to that part of the Island and reach this French steamer. Everybody says, though, a large bee, from which large quantities of honey are obtained, exists in the interior of the Island. The natives all know it by are obtained, exists in the Island. The natives all know it by the Island. The natives all know it by the name Bombera. I start for Singapore by the French steamer "Yangste," Islandary 31st. Frank Benton.

#### An Excellent Suggestion.

Prof. Cook has forwarded us for publication the annexed open letter, addressed to Dr. N. P. Allen, President of the North American Bee-Keepers' Society. The reasons adduced in support of the suggestion are well founded, and must strike all minds favorably. September and October are usually among the busiest months of the year to beekeepers and farmers, who have their later crops to garner, their honey to take off and prepare for market, their tract from a letter of Mr. Benton's, and | fruit to gather and assort, and their live the following appreciative compliment stock to be made comfortable for winter; while the date proposed by the Professor occurs just at that period when everybody can spare the time best, when traveling is the most enjoyable, and is quite late enough to enable an approximate estimate of what the harvest will be. It is competent for the Executive Committee (of which President Allen is chairman) to fix upon such time as will best subserve the interests of the Society. We trust they will give the matter an early and careful consideration. Following is the letter:

To Dr. N. P. Allen:
DEAR SIR: As the proposition which I am about to offer is of general interest to the bee-keepers of our country, I beg leave to present it through the AMERICAN BEE JOURNAL: The American Association for the Ad-

vancement of Science convenes at Cinvancement of Science convenes at Cincinnati, Ohio, on Wednesday, Aug. 17, 1881. This Association had at its last meeting, in Boston, August, 1880, more than 1,000 members present. Owing to its influence, and the large annual attendance, the local committee at the place where the meetings are to be held are able to avecure greatly reduced.

place where the meetings are to be held are able to procure greatly reduced rates on railroads leading to the place. Now, I would suggest that the North American Bee-Keepers' Association, which is to be held so near Cincinnati, convene at Lexington on Wednesday and Thursday, August 21th and 25th.

1st. This would accommodate such persons as myself, who wish to attend both meetings and could not afford time.

both meetings, and could not afford time or means were they widely separated by

time.

2d. A committee consisting of yourself.
Mr. Muth, of Cincinnati. and Mr. Wm.
Williamson, of Lexington (1 would do
what I could to aid), could act in conjunction with the local committee of the
A. A. A. of S., and I believe could get
the commutation railroad rates to extend to the Notional Res. Percent. tend to the National Bee-Keepers' Association.

3d. August is a quiet time with beekeepers, and so far as I can see, nothing would be lost in making the date of our meeting earlier than the usual time.

4th. The fact of accommodating such as wish to attend both meetings, and as wish to attend both meetings, and the reduced railroad rates, could we secure them, would greatly increase the attendance at the Bee-Keepers' Association, and would richly compensate for some loss, if such there would be.

I only make this suggestion, hoping that you and others interested will give it such consideration as its merits deserve.

A. J. Cook,

Vice Pres't of Nat. Association and President of Michigan Association.

At the Utica Convention, last month, Mr. L. C. Root was appointed a committee to endeavor to have the bill for the prevention of the adulteration of sugar, syrups, etc., then before the Legislature of New York, so amended as to include honey. We learn, with L. B. Case's Botanical Index, Richmond, Ind. - A much pleasure, that Mr. Root has succeeded in having it include honey, and Mr. R. is quite sanguine that the bill so amended will become a law of the Empire State. If passed, we hope that the bee-keepers of New York will see to it ace and died in a few hours. The assassins have been arrested. His son a "dead letter" in the statute books of that State.

#### GLEANINGS.

Bees and Grapes.-The Klassen and Krock difficulty about the bees of the former committing depredations on the grapes of the latter, is to be submitted to arbitration. It seems that the real trouble was a " personal feud that does not concern bee-keepers at all "-the grape matter was an outgrowth. This matter was referred to in Prof. Cook's article on page 74 of the Bee Journal, and should now be entirely divorced from the Bee and Grape controversy.

Bees Dead in box hives.—Mr. G. Castello, Saginaw, Mich., says that on Feb. 22 he went to a neighbor's, 5 miles distant, who had a box-hive apiary constitution of 100 calculate february. sisting of 103 colonies of bees. After looking them over they found only 10 colonies alive: all the rest had died of dysentery.

Honey for sore Eyes .- Mr. S. C. Perry, Portland, Mich., says:

"A neighbor of mine had inflammation in his eyes. He tried many things of many physicians; "was nothing better, but rather grew worse," until he was almost entirely blind. His family was sick, and I presented him with a pail of honey. What they did not eat he put in his eyes, a drop or two in each eye, 2 or 3 times a day. In 3 months' time he was able to read course urint eye, 2 or 5 times a day. In 5 limental time he was able to read coarse print, and now, after 4 months' use, his eyes are almost as good as ever. I have also are almost as good as ever. I have also found honey good for common cold-sore

## MISCELLANEOUS.

Feeding in Winter.—Mr. A. B Weed, in the Michigan Farmer, says:

"Many colonies which were put un for winter with but a small amount of for winter with but a small amount of provision, have consumed what was given them, and starved for want of more. Others have but a small amount of stores left, and must be fed soon if they are to be saved. The best way to feed such is to give them frames of well ringped honey, but this the weather ripened honey, but this the weather will not always permit. The next best thing for them is candy; this can be given at any time, and can be laid on top of the frames. If the cluster is low down in the hive, it should be put down into it, where it can be reached? into it, where it can be reached.

Bees and Grapes.-Mr. W. H. Stout, in the Lancaster, Pa., Farmer, gives the following as his experience:

By close investigation I have satisfied By close investigation 1 have satisfied myself that bees do not destroy sound grapes. I had, during the past season, 22 colonies of Italian and common black bees; all the hives were in close proximity to the grapes, while a number had the vines trained over them for shade during the heat of summer. The grapes are of the Concord variety, of which I had an abundance of fine fruit, some clusters of which grew within 18 inches of the entrance to the hives. Bunches of the grapes remained on the vines unof the entrance to the hives. Bunches of the grapes remained on the vines until the frost had killed the foliage, which fell off and left the grapes exposed, affording every temptation to the bees; and this, too, through a season when the beavey wild from natural sources was so honey yield from natural sources was so small that the bees consumed stores they had gathered earlier in the season. But the bees do work on grapes, and also on the bees do work on grapes, and also on other fruits under certain conditions. If the skin of grapes, peaches, pears, etc., is ruptured from any cause, the bees, wasps, ants, etc., are very quick in discovering it, and soon leave only the dried shells. During the hot weather of Angust especially when there are of August, especially when there are frequent showers, the skin of ripening fruit cracks, for reasons which I will leave to some philosophical friend to explain. plain. My conclusions are not hasty; nor were my observations superficial; but they were prolonged from the time discount that expression accordingly.

the first grapes ripened until the close of the season. I found some clusters of grapes literally covered with bees scrambling and fighting for the little sweets contained in the cracked grapes, which are the only ones on which they work, as I found out by driving the been way. as I found out by driving the bees away and removing from the clusters all the bursted grapes, when the bees, as soon as they found only sound fruit remained, went away and left the grapes uninjured. We also laid some bunches of grapes on top of the hives and others close to the entrances, also left clusters hanging on the vines close to the hives hanging on the vines close to the hives where they remained uninjured by the where they remained uninjured by the bees as long as the fruit was sound. I know very well that bees can gnaw through heavy muslin, or shave off wood and straw. To cover the bees we have quilts made of heavy muslin, which they sometimes bite through, and we have wood and straw hives on which they have enlarged the entrances; but, nevertheless, I am fully satisfied they do no injury whatever to sound fruit.

Feeding Rye-Meal.—In the Indiana Farmer Mr. F. L. Dougherty says:

"Bees will not raise brood without pollen in some shape. We frequently find colonies with but very little, and at times none at all. In crowding them on a few frames, quite frequently those left in the live contain but little, if any. left in the hive contain but little, if any. So it becomes necessary to furnish it to them, until they can gather it from natural sources. Unbolted rye-meal is probably the best substitute, although they will use wheat-flour, corn-meal, out-meal, or in lieu of any of these, will even carry saw-dust. To get the bees started, place a piece of comb on the meal, and if the weather be pleasant and no pollen to be had they will soon appropriate it. They will leave the meal when natural pollen makes its anappropriate it. meal when natural pollen makes its appearance.

That excellent Monthly, published in Nyon, Switzerland, by Mons. E. Bertrand,—the "Bulletin D'Apicul-teur pour la Suisse"—gives the Weekly BEEJOURNAL the following kind notice:

"We have received the first 2 numwe have received the inst 2 minusers of the American Bee Journal, which has been transferred from a Monthly to a Weekly, by its Editor, Mr. T. G. Newman. Only one apiarian publication is issued every 2 weeks, the Bienen-Zeitung of Eickstadt, That of Mr. Newman's is theyefow, the only one Newman's is, therefore, 'the only one in the entire world which is published weekly.' It is also, without doubt, the most universal. Its principal contributors are among the most distinguished bee-keepers of America, together with scientists entomologists chemists and scientists, entomologists, chemists and farmers; and the number of those who farmers; and the number of those who send it communications can be called legion. It is, with an understanding of the full extent of the services which it renders, through the abundance of the observations and of the information which it brings before its readers, that we offer to our colleague and friend our warmest felicitations on the occasion of the new development of his publication."

This warm kind notice is the more

This very kind notice is the more valuable as Mons. E. Bertrand is a man of intelligence and wealth, whose sole interest is his love of the pursuit of beekeeping.

& L'Apicoltore, the organ of the Central Societie d'Apicoltore d'Italia, also gives the BEE JOURNAL the following very kind notice, in its excellent number for February:

"The bee-papers are every day augmenting to suit the increasing need of the readers, and the publisher of the American Beejournal, Signor Newman, who came to Europe and to Milan left rear appropriate that the boring last year, announces that at the begin-ning of 1881 his Monthly JOURNAL will be issued every week."

🖙 In Mr. A. Hoke's letter, on page 77, he stated that the dead bees covered the ground for several yards. That was bad enough, but our compositor made it a hundred times worse by adding the word hundred. The reader will please

# SELECTIONS FROM

But Few Bees Lost.—We have had a pretty hard winter for bees, although 1 have heard of but few losses in this see tion. My bees are packed in chaff, and are all alive but 2 colonies, which were very weak when packed. Success to the Bee Journal. F. W. Burtnette.

Morrice, Mich., March 12, 1881.

An Old Queen.—We have had a couple of warm, bright days at last, and my bees are flying, what of them are alive. Out of 33 colonies, I think I have 10 or 12 alive, some of them pretty strong, others weak. I have 3 Italian colonies—they seem strongest. What hives I have looked into, where the bees are dead ameer to have plenty of honey. have looked into, where the bees are dead, appear to have plenty of honey; and the other bees appear to be taking the honey out, and I fear are taking from the weak colonies also. Should I prevent them from appropriating it? I noticed some drones with one of my Italian colonies; what does that mean at this time of year? I have been a short distance south, returning home 3 weeks ago. There has been great loss weeks ago. There has been great loss of bees in Fayette and Wayne counties, as well as in Wabash. Please answer above questions in the Bee Journal. Joel Brewer.

Lincolnville, Ind., March 10, 1881.

[It is not advisable to let bees have access to combs in other hives: if they need honey, put the combs in the hives where wanted, and not too many. If the strong are robbing the weaker colonies, exchange stands with them. The presence of drones thus early indicates an old or defective queen. Unless there is a large quantity of sealed worker brood (indicating the queen is perfect), we would supersede her as soon as possible, unless the bees save the trouble.

Gathering Pollen.—My bees gathered pollen lively to-day, and are strong for this time of year. My loss in wintering is 4 colonies, leaving 8 to commence the season with. Nearly all the bees in this county are dead.

JOHN C. GILLILAND.

Bloomfield Lid. March 15 1881

Bloomfield, Ind., March 15, 1881.

No Winter Flight Yet.—I am trying to winter 163 colonies in Mitchell hives. All are boxed and packed in chaff with 2 thicknesses of burlaps over the bees; the ends of the hives to the division boards are filled with chaff; combs contracted to such numbers as bees would tracted to such numbers as bees would cover. They were put into winter quarters Nov. 13, and have had no flight yet. I find many colonies affected with dysentery, and 12 are dead. It is snowing to-day with prospects of another blizzard. I cannot estimate the loss at present; will report at a future time. With many others, I am free to throw in my mite of joy for the weekly visitations of the JOURNAL.

D. VIDETO.

North Fast Pa. March 15, 1881.

North East, Pa., March 15, 1881.

Bees Confined 4½ Months.—This has been the severest winter that I can remember. My 27 colonies of bees have not had a flight since Nov. I. They are in a cellar; one of my neighbors had over 50 colonies, but there are only 5 left. He tried to winter out of doors, but has put what he had left in a cider mill. Another had over 20 colonies, wintered out of doors and lost all. I have but little hopes of having over 6 or 8 colonies; there is but little hopes of s colonies, there is but fittle hopes of having weather that bees can have a flight for 2 weeks yet. We are in a snow blockade yet. We have had but one mail in over 2 weeks. I like the Weekly better each number; it brings us nearer together and we can sympathize with our bee-keeping friends. Let us hope for the best; there are better times coming. Success to the Weekly. E. Bump.

Waterloo, Wis., March 14, 1881.

Closed out by Fire.—I had the misfortune to be "closed out" of the beebusiness by fire, on the night of March 4, losing all of my 36 colonies of Italians one of which contained an imported queen. They were all in the cellar; I also lost all the implements necessary also lost an the implements necessary to carry on the business, my house and contents. This was "closing out" rather mexpectedly, but I hope not to remain out very long.

WM. 11. TRAVIS.
Brandon, Mich., March 16, 1881.

Bees in Good Condition .- Though there is a great loss of bees bereabouts, mine are yet in good condition, and I hope will come out right in the spring. The Weekly BEE JOURNAL I value more

and more all the time.
THOMAS LASHBROOK.
Waverly, Iowa, March 11, 1881.

Lost 8 ont of 37 in Wintering.—I put 37 colonies into winter quarters, all in good condition except 4 or 5 small late good condition except 4 or 5 small late swarms, and as it was a poor season for honey, they did not fill up; 29 were packed under a shed, open to the south and east. Before packing I removed the outside frames and put in cushions made by covering empty frames with sacking and filling with chaff; also 2 inches of the same on the top of the racks. My loss to date is 3. I prepared 5 in the same manner, but left them on the summer stands; lost 4. Two that I was some would starve if not fed. I re-I was sure would starve if not fed, I removed to a room over another where a fire is kept, placed them at a window and arranged a passage leading outside; then, with wire-cloth over the frames, I can feed and examine without their flycan feed and examine without their hy-ing out. They are all right. One I left on the summer stand with a set of sec-tion boxes, unprotected, and it is very strong. On March 9th my bees had their first good flight since Oct. 25. I their first good fight since Oct. 25. I had one colony in a box hive; of course they are dead. Total loss to date, 8 out of 37. Nearly all are strong now. I am with the majority when I say that the Weekly BEE JOURNAL is a decided improvement. Success to it.

WM. MORHOUS.

Dearborn, Mich., March 14, 1881.

Sweet Clover .- Must the sweet clover be sowed over again, or does it sow itself? Please answer in the Weekly BEE JOURNAL, which I could not do without. It is the best bee paper that is published. Lewis Siegm. Newstadt, Ont., March 11, 1881. LEWIS SIEGMAN.

[A good "stand" of sweet clover will sow itself, as there are generally some seeds that do not catch the soil the first season, but germinate the second. It is more satisfactory, however, to plant the second season about half the complement put in the first, after which it will bloom annually, and sow itself.  $-E_{D,1}$ 

Had a Flight in January.—In the winter of 1879 I put 30 colonies into my cellar; but it was so warm that they were uneasy and I put them back on the summer stands. I lost 10 colonies; I now have 20 colonies, facing the south. I now have 20 colonies, facing the south, sheltered by a board fence on the north and covered with about 18 inches of straw. About 10 days ago they had a nice flight, and I covered them up again. I think of building a house for them facing the south, and boarding up the other 3 sides; I will then cover the hives with about 2 feet of straw, which I can remove on a bright day and give them a flight. I intend to leave the straw on them until warm weather, and thus aid them to keep warm for brood rearing, &c. I wish the BEE JOURNAL success.

T. RICE. Lenox, Ill., Feb. 4, 1881.

Nearly All Dead.—Bees are nearly all dead in this region.—I had 33 colonies last fall and now have but 10;—a neighbor had 40 and now has none; another had 44 and now has 2; another had 75, and 3 weeks ago they were reduced to 20. Several have lost all but 1 or 2, and some have lost all.

WM. S. BUCHANAN.

Hartford, Ind., March 14, 1881.

Bokhara Clover .- Please answer the ollowing questions in the Journal:

1. When is the best time to sow Bok

hara clover?

2. Should it be sown alone or with a grain crop, or with other kinds of clover?

3. Should it be cut for hay, pastured, or kept for bees only?

4. Which is the best kind of hive for

comb honey—a one-story with racks to hold sections, or a two-story, with section boxes put in cases in the upper story?

JOHN H. HEARD. Ffesherton, Ont.

[1. Early in spring is as good a time as any for planting Bokhara, melilot or sweet clover-we fail to discover any difference in them.

2. For bees alone, sow it alone.

3. If desired for cattle or sheep, sow it with timothy, letting them graze it, as it blooms but little the first season: afterward keep them off.

4. One-story with rack is more easily manipulated.—ED.1

An Enthusiast.—My apiary is located on a hill-side sloping to the west, and hives fronting south. The Macoupin creek is ½ mile south of it, and several sloughs within a mile, with plenty of soft and hard maple, willows and cotton-wood. I packed rags around and on top of my 13 hives, on their summer stands, on the 25th of October. The bees were in good condition. Only one colony gave any surplus; from that I took 40 lbs., and left them 35. I examine my bees every week and clean out the dead bees every week and clean out the dead ones. They had a good flight on the 13th ones. They had a good night on the lath of December, and again on Feb. 22d, when every colony had brood in all stages, and No. 2 was crowded full of young bees, and had a queen cell just ready to put the egg in, which I took off. Each of the was a warm day, and No. off. Feb. 26th was a warm day, and No. 2 sent out a swarm; it was queenless, however, so I sprinkled them with peppermint water and united them with permint water and united them with No. 12, which was weak. I do not keep bees for profit in dollars and cents, but for pleasure, as I do love them. I am a merchant, and own 275 acres of land, but being an invalid, look to my bees for recreation. In a radius of 4 miles from my apiary, on Nov. 1st, there were 13 bee-owners, with a total of 73 colonies. On the left inct. there were 19 colonies. On the 1st inst. there were 19 colonies left, and they were in bad condition. I am the only one taking the BEE JOURNAL here—success to it.
R. M. OSBORN.

Kane, Ill., March 4, 1881.

Bees All Dead.—I now send you my report for the winter of 1880-81, which will long be remembered by the beekeepers in this locality. I commenced the winter with 9 colonies of bees, all carefully packed in chaff on the summer stands with plenty of nice sealed honey. They were packed on the 13th day of last Nov., and from that until the present time (121 days) there has not been a single day that the bees could safely fly, and the consequence is my bees are all dead, from the effects of their long confinement. They left plenty of honey, but the combs are badly soiled. I am not discouraged, however, and shall try again. A gentleman living not far from here had only 8 colonies left out of 39, 2 weeks ago, and when spring condescends to smile on us again we think it will not need a returning board to count the bees in this county. I am well pleased with the new Weekly it is always. bees in this county. I am well pleased with the new Weekly; it is always a welcome visitor.

J. R. Kilburn.

Fisher Station, Mich.. March 14, 1881.

Bees Robbing.-Here in Texas we have had a severe winter, but not much the eellar for 118 days, have wintered well so far, but are becoming uneasy.

20° above zero. Last season was a poor one for honey; we had a cold spell in Nov.; then had warm weather for 2 weeks, and my hybrid bees began to rob. The pure Italians behaved well, neither robbed nor let the others rob them. I used water and kerosene oil, but it was of no use; at last 1 hit upon a remedy. My hives have the bottom boards projecting in front. I ripped out one-inch square pieces 5 inches long, cut coarse wire cloth 2x6, bent it

lengthwise in the middle, tacked on 2 sides of each block, leaving wire about 5 inches to give them air; I drove a nail 5 inches to give them air; I drove a nail through each end and nailed it in front of each hive. Every 10 or 15 days when the weather was fine, an hour before night. Het them out to have a fly. We have had fine weather for the last 2 weeks. I let the bees out on Jan 30; they have been busy carrying in pollen from elm since Jan. 3), and have forgotten their stealing womensities. opened some hives this evening and found plenty of sealed brood, and will have drones flying by Feb. 24.

J. W. ECKMAN.

Richmond, Texas, Feb. 10, 1881.

Chloroform.-About 10 years ago I used chloroform in handling bees, after the following plan: 1 provided myself with a tin slide about 5 inches long and a wide; punched a few holes in it, and stitched on one side of it a pad of 3 or 4 thicknesses of cotton cloth. Then af-ter closing all ventilators and entrances ter closing all ventilators and entrances except the lower one, I turned about one teaspoonful of chloroform on the pad and slipped it through the entrance, and immediately closed the hive with a wad of cloth, I then listened carefully until the bees had nearly ceased humming (or about 1 or 2 minutes) and then opened the hive and withdrew the slide. They were cross withdrew the slide. They were cross hybrid Italians. P. F. WILLCOMB.
Lancaster, Wis., March 5, 1881.

Test for Honey.—Bee-keepers need a good honey test, to expose the "rag syrup," an admixture of honey and glucose, with which the New York market cose, with which the New York market is flooded. In every grocery, meat market and drug store there, can be found cans of "Walker's best honey," labeled "Greenpoint, N. Y.," but there is not much honey in it. Last fall I went into a drug store there with 4 samples of my best honey. They tested it, and what they used turned it perfectly black. I saw one of Walker's cans of honey there, and asked them to test that; they did so, but the same drugs had no effect did so, but the same drugs had no effect whatever on that. They would not tell me what they used to test it; but I would like to have a good and simple test given in the Bee Journal.

Sing Sing, N. Y. H. RICHEY.

[Pure green tea, well steeped, is used by many to detect the presence of glucose in honey. If the honey dissolves without changing the color of the tea. it is supposed to be pure. But in these days of "enterprise," it is frequently a matter of doubt whether the tea is pure; again, if, as is claimed, glucose is sometimes manufactured without leaving sulphuric acid or other deleterious substances in it, then the tea would hardly expose it when mixed with honey. Alcohol is also used to detect the presence of glucose; but besides being frequently inconvenient to obtain, it requires considerable skill in its use.

Thousands of bee-keepers will unite with us in thanking Prof. Kedzie, of the Michigan Agricultural College, for a simple test to detect adulterations in honey and syrnps, and instructions for its application.-ED.1

Three Fourths of the Bees Dead .- The the bees in this section. Bees have not had a thorough cleansing flight since Nov. 8. One apiary of 61 colonies, well packed in chaff and plenty of good stores, will not go through with over 50 per cent. Mine have been confined in the cellar for 118 days, have wintered well so far, but are becoming uneasy.
M. A. Gill.

Bees Doing Well.—My bees had a nice flight on the 9th, 10th and 11th of this month and are now doing well. It is month and are ... cold again to-day.

J. R. WAGGONER.

Grantville, Kan., March 12, 1881.

Dwindling in the Cellar.—I put 53 colonies in the cellar, in good condition, which are all alive but one; but there are a great many dead bees with tom of the cellar—more than I ever knew before. I gather them up and carry them away occasionally, to preare a great many dead bees on the botvent their tainting the air. Will the loss of so many weaken the colonies, and what is the cause of it? My bees have not seen the light this winter, yet they seem all right excepting the loss of so many on the cellar bottom.

WM. F. STANDISH.

Evansville, Wis., March 9, 1881.

[If the colonies were very strong, the loss may not be appreciable. The cause may be attributed to age of the bees when put away, and subsequent long confinement: or the cellar may have been too warm at times, and the bees become uneasy.—ED.]

Contradictory Experience.—The poor bees have suffered dreadfully in this locality, and the circumstances and conlocality, and the circumstances and conditions under which some have perished and others survived the past Irying season, are so varied that I am quite at a loss what to think about bee preservations the wintergroups I had 19 foss what to think about bee preserva-tion during the winter season. I had 12 colonies last fall; I packed 6 with chaff 6 inches thick around them, and have 1 colony left of the lot. There is honey colony left of the lot. There is honey in the combs, but the bees are all dead, I put 3 colonies in the celar; 2 of them are alive, but in a bad condition, the combs being dirty and moldy. I left 3 on the summer stands, and 1 is yet alive. None died for want of honey; there was plenty of food for them in the hives. The 6 were put into the chaff in the latter part of November, and taken out on the 8th of March. The combs look clean and free from mold. About a week before I took them out of the chaff clean and free from mold. About a week before I took them out of the chaff I had taken off the front boards, and finding the bees alive, shut them up again. Upon taking them out this was the only colony that was alive. When I took the chaff off, the bees were crowded around the entrance ready to fly which they did at once and had a fly, which they did at once, and had a lively time until they were driven inside by the approach of night. Do you think the other 5 colonies were dead the first time I looked at them. They had a time I looked at them. They had a passage through the chaff I inch high by 4 wide. A friend of mine here had 4 colonies wintered outside, with an old piece of sail-cloth over them, and only lost one, while old bee-keepers, with between 50 and 100 colonies, have lost one-half, and others have lost all.

F. A. HUTT. South Bend, Ont., March 11, 1881.

[Your question is a stunner; we have no data on which to base an intelligent opinion.-Ep.1

Wintered Without Loss,-My 27 colonies came through the winter without the loss of a single one, for which I can the loss of a single one, for which I can thank 4 or 5 colonies of Italians, for without them I should not have had honey enough to have kept them through, even a moderate winter, to say nothing of such a stinger as we have had. I have withheld my opinion in regard to the change in the JOURNAL frame, monthly the workly fill thad from a monthly to a weekly till I had tried it a couple of months, and will now say that it would be a great disappointment if you were to go back to a monthly. I am glad that you have so often devoted your first page in each number to the subject of bee-pastnrage, for that is, or should be, our leading study now till we are or street ground. study now, till we are on surer ground. The best way to make bee-keeping popular is to make it pay; and it will pay if we can get the pasturage every year. 1 would rather have a tip-top honey plant than an Apis dorsata, if it had a tongue long enough to lick the molasses out of the bottom of a 5 gallon keg. We sha have plenty of white clover this year,

WM. CAMM.

Murravville, Ill., March 12, 1881.

Bees Uneasy in the Cellar. - This has been a very hard winter for bees in this section of the country. Nearly all the bees are dead that were left on the summer stands. I have 40 colonies in the cellar, all alive but restless. They need a cleansing flight very much. The Weekly BEE JOURNAL pleases me very much. Chas. II. Dow.

Freedom, N. Y., March 12, 1881.

Bees Much Better Than Expected. My bees are much better than I had any reason to expect. I left them on their summer stands, and did not even take the tops off, but I have them all off now. I had about 80 and now have 70 colonies in good shape. I find I must either attend to my bees or quit the business. and have made arrangements with a and have made arrangements with a friend who has about the same quantity, who will take charge. We shall call it the "Gipsy Apiary," and our motto will be, "if the honey will not come to us we will go to the honey." Mr. Heddon thinks it wont pay to move for honey, and he is pretty good authority, but we will try. Keep us posted through the JOURNAL where is posted through the Journal where is the best place to sell honey. Keep the ball rolling in the suppression of adulterated honey, as well as other adultera-tions.

I. II. SHIMER. Hillsboro, Ill., March 14, 1881.

Have Young Bees and Brood.-1 put and now have 13 in fair condition; some had young bees 2 weeks ago, and all of them have brood. The last 2 years have been very poor for bees; the last the worst, being followed by such a cold and About one half of the bees in this locality are dead.

Moore's Hill, Ind., March 14, 1881.

Bees in the Cellar 135 Days. colonies of bees out for a flight on irch 8. This is the first suitable day March 8. This is the first suitable day for bees to fly there has been here since they were put in the cellar on the last of Oct. They came through the 4½ months' confinement very well, except 2 or 3 third-rate colonies that had more hive room than they could well keep warm through this cold winter, and now warm through this cold winter, and now they seem to be somewhat reduced in numbers. The day was rather cold, snow did not soften in the shade but the sun shone brightly, "the winds were asleep," and the bees seemed to enjoy the fray, but left a good number of the slain on untrodden snow. They were returned to the cellar at night and will be smalled with water in their bires. be supplied with water in their hives, hoping to secure the starting of a good cluster of brood before they are placed on their summer stands, about the 1st of May. I usually keep them in confinement without a flight for 5 or 6 months, with good results, but in 1879 brood rearing ceased about the 1st of Sept.; the hives were destitute of brood when carried out. April 18, and although the hivestilled rapidly with brood, before it began to hatch nearly all the old bees began to natch hearly all the old bees were dead, giving me the most disastrous case of spring dwindling that I have known in an experience of 25 years. I hope to avoid such losses in the future.

A. Webster.

E. Roxbury, Vt., March 10, 1881. have known in an the future

The Best Honey for Winter.—By this time I presume all the readers of the BEE JOURNAL know that the winter has been quite severe—about as destructive to the older people as to bees. Bella Lincoln, the oldest bee-keeper in this section of the country, died this winter, and since then nearly all of his 100 colonies of bees have also died. My 100 colonies of bees have also died. My 60 colonies are in the cellar with chaif over the frames; some are dead, and the entrances to others are soiled, indicating dysentery. Several which had scaled honey stored in the summer are all right. Some worked on a cider all right. Some worked on a cider mill, but if they have good sealed honey I do not think it makes so much difference about the kind of winter. the Weekly BEE JOURNAL, because it "enthuses" me every time I read it. In any kind of business one needs some enthusiasm, at least once a week. C. F. SMITH, JR.

Vandalia, Mich., March 12, 1881.

bees wintered well on summer stands, in double-walled Langstroth bives. are carrying in dark pollen to-day; I think they get it from the maple.

II. II. LITTELL. Lonisville, Ky., March 5, 1881.

Chaff-Packing of Bees Triumphant.— The winter has been a severe one everywhere. Since the 1st of Nov. until the where. Since the 1st of Nov. until the first days of this month my bees had not had a flight. I live in a very high altitude, about the highest good land in the State. The winter begins early and lasts long. We have an abundance of snow now and it is blustering wildly today. I desprised of section my back I despaired of seeing my bees come out alive; they were covered solidly with snow for 3 months, only the tops of the hives being visible. At last the weather softened and I dug away the snow. The next day or 2 the sun came out warmly and my bees began to the and greatly than when y disparent. fly, and greatly to my happy disappointment they are all alive—all that I had out on the summer stands. One only was dull, which I examined and found was diff, which I examined and reads enfeebled with dysentery, arising from the feed I gave them in the fall. All others were strong. Just 122 days had intervened between the flights. The intervened between the flights. The sick colony has since died, but the others are in the best condition. This success is a tribute to the chaff-packed hive. Is there another record of 122 days' continement and yet come out

W. S. Blaisdell. Randolph, Vt., March 11, 1881.

Look out for the Robbers.—We have had a very hard winter on bees in this section of the country. Bees that were not properly packed for winter are nearly all dead, while those that were properly packed are nearly all in good condition. We are having good weather now and the bees are flying nicely. Those having weak colonies and hives of counter nithent have those will have to leak. Look out for the Robbers.—We have of combs without bees will have to look out for robbers and keep their small colonies crowded upon as few combs as they can, keeping the entrance con-tracted, so that only 1 or 2 bees can en-ter at one time. Hives in which the died should be closed tightly. The Weekly BEE JOURNAL is a welcome visitor. I could not think of doing without it. J. A. OSBORNE.
Rantoul, Ill., March 17, 1881.

Two-thirds of the Bees have Died .-Over 3 of all the bees in this part of the State are now dead. I have met with a heavy loss, on account of a cider mill that was within 80 rods of mapiary last fall. 111RAM ROOP.

Carson City, Mich., March 12, 1881.

Bees in Good Condition. - We put out on the summer stands on the 9th and 10th of March, 150 of our 200 colonies that we had in the cellars in good condition. These were the first days that bees could fly with safety since the first of Nov. We have 50 colonies more in one cellar, but as they seem to be doing cellar, but as they seem to be doing well, we shall leave them in until it becomes settled weather. We left 9 colonies on their summer stands but the winter was so long and severe that we could not feed them and 3 of them starved. Now we are busy transferring, that is shaking the bees off the combs, cleaning them off and putting them in-to clean hives. If we find any not strong enough we double them up. We conenough we double them up. We consider ourselves nearly masters of the wintering question as our real losses for the last 10 years, we think, would not exceed 6 per cent.; in fact we did not lose a colony in winter or spring, until the number had reached about 100. The BEE JOURNAL is a welcome Weekly visitor.

T. S. BULL & SON. Valparaiso, Ind., March 15, 1881.

Death Reigns among the Bees. ing made some inquiry concerning the bees within a radius of about 2 miles, 1 ind some bee-keepers, some who keep bees, and those that let the bees keep themselves. Mr. II. had 3 colonics, all are dead; Mr. L. had 7, one left; Mr. D. left his 11 colonies without protection that is the colonies without protection without protection. and now has 11 empty lives for sale;

Carrying in Pollen,—My 5 colonies of Mr. B. let the winters' blast try his 20 colonies and now has 12 empty hives; Mr. F. packed 37 in chaff and has 11 left; Mr. A put up 57 in complete order, Mr. F. packed 37 in chaff and has 11 left; Mr. A put up 57 in complete order, but with all his precaution all are dead; Mr. B. put into winter quarters 73 colonies of fine Italians, 58 of them are dead. I packed in clover-chaff 101 colonies, and 23 have gone the way of all the earth. My bees were confined in their hives from Oct. 20 until March 6. I packed 24 in Langstroth hives with space the whole width of hive left open, to give plenty of fresh air, yet at the space the whole wheth of his reference, to give plenty of fresh air, yet at the same time warm, with a due amount of packing, and in this lot have not lost one colony, and very few bees; but the end is not yet. To-day I found young hear with freed in all attages.

bees with brood in all stages.
G. W. NAFTZGER.
South Haven, Mich., March 17, 1881.

No Loss in Wintering.—Nearly all the bees in this vicinity that were left to care for themselves are extinct. 14 colonies packed comfortably in chaff before the cold weather commenced, and have not lost any yet. I am highly pleased with the Weekly BEE JOURNAL. pleased with the mean. and wish it great success.

J. P. Moore.

Morgan, Ky., March 14, 1881.

Poor Season but Fair Profit.-After selling my surplus colonies. I commenced the season of 1880 with 37 colonies in fair condition; increased by division and natural swarming to 63, and 12 nuclei. I reared 30 Cyprian and Italian queens; had 100 Gallup frames of foundation drawn out, and extracted 400 lbs. of honey. Estimating the increase at \$6 per colony, and deducting the expenses my income for care and the expenses, my income for care and labor is \$250, or about \$6.50 for each colony in the spring. I put 75 colonies, in fair condition (including the 12 nuclei), into winter quarters Dec. 8; some were short of stores, and all had poor honey. On March 1st I found 8 colonies honey. and 4 nuclei dead—4 starved and 8 died from the effect of poor honey and long confinement. More of them are diseased and nust have a fight soon or die. With the loss of stock already mentioned, and allowing for more to follow, the credit will be cut down to \$3.50 per colony. The season has been the poorcolony. The season has been the poorest I ever knew, but even \$3.50 is a fair profit on the investment. White clover gave no honey; basswood lasted only 10 days, but yielded well; had it lasted 2 weeks longer I should have had an average yield of honey for the season. Without this flow of basswood honey, the bees must have been fed, but now the bees must have been red, but how they have enough stores to carry them through till spring. As the heavy snows have no doubt preserved the clover, the outlook for honey this summer is good. I hardly need say that I am pleased with the Weekly BEE JOURNAL.

T. E. TURNER.

Sussex, Wis., March 1, 1881.

Planting Buckwheat for a Honey Yield.

—In answer to Mr. A. Hodges, on page 78, I will say that buckwheat is a peculiar plant about yielding honey. I have never known it to fail here in yielding enough honey for the bees' winter stores, and usually very much more; in other localities in the same latitude, it cannot be relied on at all for a honey cannot be relied on at all for a honey crop. It seems, however, that it never yields through the entire season in which it can be made to bloom. Quite a large amount of it is cultivated every season in my vicinity, much of it generates a large amount of it is cultivated every season in my vicinity, much of it generally coming into full bloom as early as the middle of July, yet I have never known it to yield any honey earlier than the 1st of August, and very rarely before the 10th; but when it commences to yield honey, it does so profusely until the plant fiself is ripe, or killed by frost. I would say to Mr. Hodges, or any one else intending the sowing of successive erops of buckwheat, that it is useless to sow any early in the season, to blossom sow any early in the season, to dissomble to the 1st of August. I am intending to sow about 20 acres of it this season for my bees. I shall put the first crop of it in the ground about June 25; the rest about July 10. That from the last serving will remain in bloom put? Williamstown, Iowa, March 9, 1881.

#### CLUBBING LIST.

We supply the Weekly American liee Joarnal and any of the following periodicals, for 1881, at the prices quoted in the last column of figures. The first column gives the regular price of both:

The Weekly Bee Journal (T. G. Newman) \$2.00 and Gleaningsia Bee-Culture (A.I.Rout) \$4.00 and Gleaningsia Bee-Culture (A.I.Rout) \$4.00 and Gleaningsia Bee-Culture (A.I.Rout) \$4.00 colors (C. 2.75 and C. 2.75 and For Semi-monthly Bee Journal, \$1.00 less. For Monthly Bee Journal, \$1.50 less.

### Honey and Beeswax Market.

BUYERS' QUOTATIONS.

CHICAGO.

HONEY-The market is plentifully supplied with honey, and sales are slow at weak, easy prices. Quotable at 1825c. for strictly choice white comb in 1 and 21b. boxes; at 1404fec. for fair to good in large puckages, and at 1942c. for common dark-colored and broken lots. Extracted, %61fc.

BEESWAX.-Choice yellow, 20623c; dark, 15617.

NEW YORK.

HONEY.—Best white comb honey, small near packages, 14@16c.; fair do., 14@16c.; dark do., 11@12-large hoxes sell for about 2c. under above. White extracted, 9@10c.; dark, 7@8c.; southern strained

BEESWAX.—Prime quality, 20@23c.

CINCINNATI.

HONEY.—The market for extracted clover honey is good, at 80 10c. Comb honey is of slow sale at 16c. for the best. BEESWAX—18@22c. C. F. MUTH.

SAN FRANCISCO.

SAN FRANCISCO.

HONEY.—The "Vigilant" takes 600 cases to Liverpool. There is a slightly improved feeling consequent upon a little more inquiry, but prices show no material appreciation. Discouraging reports are received from the southern part of the State, as to the prospects of the coming crop, but other sections give promise of an abundant yield. With a good supply yet on the market, prices are not apt to be buoyant until the anticipated failure is more fully settled. We quote white comb. 126/18c; dark to good, 96-41c. Extracted, choice to extra white, 55-64-65c; dark and candied, 56-54-6c.

BEESWAX—229/214c, as to color.

andied, 5% 5½c. BEESWAX+22@22½c., as to color. STEARNS & SMITH, 423 Front Street. San Francisco, Cal., March 11, 1881.

## SPECIAL NOTICES.

© Constitutions and By-Laws for local Associations \$2 per 100. The name of the Association printed in the blanks for 50 cents extra.

"What is the meaning of 'Dec. "What is the meaning of 'Dec. 81' after my name on the direction-label of my paper?" This question has been asked by several, and to save answering each one, let us here say: It means that you have paid for the full year, or until "Dec. 31, 1881." "June 81" means that the first half of the year is paid for, up to "July 1st." Any other month, the same.

We will send sample copies to any who feel disposed to make up clubs for 1881. There are persons keeping bees in every neighborhood who would be benefitted by reading the JOURNAL, and by using a little of the personal influence processed by about the way of the personal inand by using a little of the personal influence possessed by almost every one, a club can be gotten up in every neighborhood in America. Farmers have had large crops, high prices, and a good demand for all the products of the farm, therefore can well afford to add the BEE JOURNAL to their list of papers for 1881.

When changing a postollice address, mention the old address as well as the new one.

We have prepared Ribbon Badges for bee-keepers, on which are printed a large bee in gold. Price 10 cents each, or \$8.00 per hundred.

The Volume of the Bee Jour-NAL for 1880, bound in stiff paper covers, will be sent by mail, for \$1.50.

We Notices and advertisements intended for the Weekly BEE JOURNAL must reach this office by Friday of the week previous.

Instead of sending silver money in letters, procure 1, 2 or 3 cent stamps. We can use them, and it is safer to send such than silver. such than silver.

Ladies who Appreciate Elegance and purity are using Parker's flair Balsam. It is the best article sold for restoring gray hair to its original color and beauty.

The date following the name on The date following the name on the wrapper label of this paper indicates the time to which you have paid. In making remittances, always send by postal order, registered letter, or by draft on Chicago or New York. Drafts on other cities, and local checks, are not taken by the banks in this city except at a discount of 25c., to pay expense of collecting them.

Premiums.—For a club of 2, weekly we will give a copy of "Bee-Culture;" for a club of 5, weekly, we will give a copy of "Cook's Manual," bound in cloth; for a club of 6, we give a copy of the Journal for a year free. Do not forget that it will pay to devote a few heaves to the Beauty Manual. hours to the BEE JOURNAL.

BEE JOURNAL will be sent free to any names that may be sent in. Any one intending to get up a club can have sample copies sent to the persons they desire to interview, by sending the names to this office. names to this office.

Any one desiring to get a copy of the Constitution and By-Laws of the National Society, can do so by sending a stamp to this office to pay postage. If they desire to become members, a fee of \$1.00 should accompany it, and the name will be duly recorded. This no-tice is given at the request of the Exec-utive Committee.

It would save us much trouble, if all would be particular to give their P.O. address and name, when writing to this office. We have several letters (some inclosing money) that have no name. Many others having no Postoffice, County or State. Also, if you live near one postoffice and get your mail at another, be sure to give the address we have on our list. dress we have on our list.

At the Chicago meeting of the Na-FAt the Chicago meeting of the National Society we were requested to get photographs of the leading apiarists, to sell to those who wanted them. We can now supply the following at 25 cents each: Dzierzon, the Baron of Berlepsch, and Langstroth. The likeness of Mr. Langstroth we have copied, is one furnished by his daughter, who says, "it is the only one ever taken when he was in good health and spirits." We are glad to be able to secure one of such a satisfactory nature. a satisfactory nature.

and by using a little of the personal influence possessed by almost every one, a club can be gotten up in every neighborhood in America. Farmers have had large crops, high prices, and a good demand for all the products of the farm, therefore can well afford to add the BEE JOURNAL to their list of papers for 1881.

HUNDREDS OF MEN, WOMEN AND CHILDREN rescued from beds of pain, sickness and almost death and made strong and hearty by Parker's Ginger Tonic are the best evidences in the world of its sterling worth. You can find these in every community.—Post. See advertisement. 9w4t

My Annual Catalogue of Vegetable and Flower Seed for 1881, rich in engravings from photographs of the originals, will be sent FREE to all who apply. My old customers need not write tor it. I offer one of the largest collections of vegetable seed ever sent out by any Seed House in America, a large portion of which were grown on my slessed farms. Full directions for bed by ackage. A for, that should it prove otherwise, I will refill the order gratis. The original introducer of the Hubbard Squash, Phinney's Melon, Marblehead Cabbaces, Mexican Carn, and scores of after vegetables. I invite the patronage of all who are anxious to have their seed directly from the grower, fresh, true, and of the very best strain.

## Books for Bee-Keepers.

Quinby's New Hee-Keeping, by L.C. Root.— The author has treated the subject of bee-keeping in a minner that cunnot full to Interest all. Its style is plain and forceble, making all its readers sensible of the fact that the author is really the master of the author that the master of the subject. Price, \$1.50.

Novice's A 15 Cofffee-Culture, by A. I. Root, This embraces "everything pertaining to the enre of the honey-bee," and is valuable to beginners and those more advanced. Cloth, \$1,25; paper, \$1.00.

King's Hee-Keepers' Text-Book, by A. J King.—This edition is revised and brought down to the present time. Cloth, \$1.00; paper, 75c.

Langstroth on the Hive and Honey Hee. This is a standard scientific work. Price, \$2.00.

This is a standard scientific work. Price, \$2.00.

Blessed Hees, by John Allen.—A romance of bee-keeping, full of practical information and contagious enthusiasm. Cloth, \$1.00.

Bee-Colliture; or Successful Management of the Aphrey, by Thomas G. Newman.—This pamphlet embraces the following subjects: The location of the Aphrey-Honey Plants—Queen Rewring—Peeding—Swarming—Dividing—Transferring—Intelnal and Handling Bees—The Newest Method of Preparing Honey for Market, etc. It is published in English and German. Price for either edition, 40 cents, postpaid, or \$3.00 per dozen.

Food Adulteration; What we cat and should not cat. This book should be in every family, where it ought to create a sentiment against the adulteration of food products, and demand a law to protect consumers against the muny health-destroying adulterations offered as food. 200 pages. Paper, 50c.

The Dzierzon Theory;—presents the funda-mental principles of bee-culture, and furnishes a condensed statement of the facts and arguments by which they are demonstrated. Price, 15cents.

which they are demonstrated. Price, 15 ccots.

Honey, as Food and Medicine, by Thomas G. Newman.—This is a pamphlet of 24 pages, discoursing upon the Ancient History of Bees and Honey; the nature, quality, sources, and preparation of Honey for the Market; Honey as an article of food, giving recipes for making Honey Cakes, Cookies, Puddings, Foam, Wines, &c.; and Honey as Medicine, followed by many useful Recipes. It is intended for consumers, and should be scattered by thousands all over the country, and thus assist in creating a demand for honey. Published in English and German. Price for either edition, Ge.; per dozen, 50e.

Winterlog Hees.—This pamphlet contains all the Prize Essays on this important subject, that were read before the Centennial Bee-Keepers' Association. The Prize-425 in gold-was awarded to Prof. Cook's Essay, which is given in full. Price, 10c.

The Hive I Use—Being a description of the hive used by G. M. Doolittle. Price, 5c.

Extracted Honey; Harresting, Handling and Marketing.—A 24-page pamphlet, by Ch. & C. P. Dadam, Hamilton, Ill. This gives in detail the methods and management adopted in their aplury. It contains many good and useful hints, and is well worth the price—15c.

Practical Hiotato Ree-Keepers, by Chas. F. Muth. Channati, Ohio; 32 pages. This pamphlet gives Mr. Muth's views on the management of bees, and embraces several of his essays given at Conventions, etc. It will be read with interest by beginners as well as those more advanced in the science of beeculture. Price, 10c.

Kendall's Hurse Hook—No book can be more useful to horse owners. It has \$\frac{3}{2}\$ engravings, illustrating positions of sick hoses, and treats all diseases in a plant and comprehensive manner. It has a large number of good recipes, a table of doses, and much other valuable horse information. Paper, 25c.

other valuable norse information. Paper, 25c.

Chicken Cholera, by A. J. Hill,—A treatlse on its cause, symptoms and cure. Price, 25c.

Moore's Universal Assistant contains information on every conceivable subject, as well as receipts for almost everything that could be desired. We doubt if any one could be induced to do without it, after having spent a few hours in looking it through. It contains 480 pages, and 500 engravings. Cloth, \$2.50.

Ropp's Easy Calculator.—These are bandy tables for all kinds of merchandise and interest. It is really a lightning calculator, nicely bound, with slate and pocket for papers. In cloth, \$1.00; Morocco, \$1.50. Cheap edition, without slate, 50c.

Sent by mail on receipt of price, by

THOMAS G, NEWMAN, 974 West Madison Street, Chleagn, 111.

## Binders for the Bee Journal

of 1881, cloth and paper, postpald, 85 ccots.

We can furnish Emerson's Binders, gilt lettered on the back, for AMERICAN BEE JOURNAL for 1800, at the following prices, postage paid:

We can also furnish the Binder for any Paper or Magazine desired.

THOMAS G. NEWMAN, 974 West Madlson Street, Chleago, Ill.

### Bee-Keeping in Ceylon.

We acknowledge, with thanks, the receipt of two copies of the Ceylon Observer, from J. Matthew Jones, Esq., of Halifax, Nova Scotia, who kindly sent them to us after having received them from a friend in that far-off island. They contain articles on the bees of Ceylon. In one of them the editor remarks as follows:

We are much indebted to our visitor, Mr. Frank Benton from the United States, for calling public attention in so States, for calling public attention in so interesting and practical a manner to a subject which has been too long neglected in Ceylon.... It is far from creditable to the natives of Ceylon and other comparatively permanent residents in the island that no systematic attempts have been made to utilize the honey-making been accommand in our furner. have been made to utilize the honey-making bees so common in our forests. Mr. Benton has formed a very high opinion of the small island bee (Apis Indica) and it is purely from his interest as an apiarist that he has come forward to remind us of the value of a totally neglected industry. Cyprus, at this moment, has over 30,000 bee-hives in full operation, and official tradition has it that the number once exceeded has it that the number once exceeded 200,000. Mr. Benton is evidently of opinion that if the Sinhalese villagers as well as town residents took up the business with good will and intelligence, the "spicy island" could very soon be-come no mean rival to the classical isand of Asia Minor. Be this as it may, we trust the subject will not be lost sight of by our Government Agents and their subordinate headmen. Our lowcountry rural population wants an offi-cial leading, and this could come through

to the best mode of bee-keeping and honey-harvesting ought to be printed and circulated in the vernacular. Some years ago attention was called to the subject of "bee-keeping in Ceylon" in the columns of the Observer, but we cannot recall the date of the communication. Meantime as of interest in conreaction. Meantine as of interest in connection with Mr. Benton's paper we republish all that appears in Tennent's "Natural History of Ceylon" on the subject of bees:

Bees,--Bees of several species and genera, some unprovided with stings, and some in size scarcely exceeding a houseor suspend their combs from a branch. The spoils of their industry form one of the chief resources of the uncivilized Veddahs, who collect the wax in the upland forests, to be bartered for arrow points and clothes in the lowlands.

A gentleman connected with the department of the Surveyor General (Mr. W. Ferguson) writes to me that he measured a honey comb which he found fastened to the overhanging branch of a small tree in the forest near Adam's Peak, and found it 9 links of his chain or about 6 feet in length and a foot in breadth where it was attached to the branch, but tapering towards the other extremity. "It was a single comb with extremity. "It was a single comb with a layer of cells on either side, but so weighty that it broke the branch."

I have never heard of an instance of persons being attacked by the bees of Ceylon, and hence the natives assert, that those most productive of honey are destitute of stings.

The Carpenter Bee.—The operation of the most interesting of the tribe, the Carpenter Bee, I have watched with admiration from the window of the Colonial Secretary's official residence at Kandy. So soon as the day grew warm, Kandy. So soon as the day grew warm, these active creatures were at work perforating the wooden columns which supported the verandah. They poised themselves on their shining purple wing, as they made the first lodgement in the wood, enlivening the wood with an uninterrupted hum of delight which was audible to a consierable distance. When the excavation had proceeded so far that the insect could descend into it the music was suspended, but renewed the music was suspended, but renewed from time to time, as the little creature came to the orifice to throw out the chips, to rest, or to enjoy the fresh air. By degrees a mound of sawdust was formed at the base of the pillar consistformed at the base of the pillar consisting of particles abraded by the mandibles of the bee. These when the hollow
was completed to the depth of several
inches, were partially replaced in the
excavation after being agglutinated to
form partitions between the eggs, as
they were deposited within. The mandibles of these bees are admirably
formed for the purpose of working out
the tunnels required, being short, stout,
and usually furnished at the tip with 2
teeth which are rounded somewhat into teeth which are rounded somewhat into the form of cheese-cutters. These, when brought into operation, cut out the wood in the same way as a carpenter's double gouge, the teeth being more or less hollowed out within. male alone is furnished with these powcial leading, and this could come through the village headmen or the village headmen or the village school-master, or both, if only the hint those of the females. The bores of some were given through superior authority.

At the same time simple instructions as

Mr. Benton's paper is as follows:-

#### The Introduction of Bee-Culture into the Island of Ceylon.

During a short stay in Ceylon, I have made diligent inquiry in this part of the Island regarding the honey bee found here and have also endeavored to learn whether any bees were kept in hives or not. In the vicinity of Galle, I found no bees, except the wild bees in the jungle. When asked why they did not keep bees, the natives invariably replied: "It is too much trouble." But I do not think they know how to manage these insects. I was told that in the interior, bees were kept in earthen pots or jugs, a statement which was, however, contradicted by most persons with

whom I talked.

There is no reason why a region so productive as the Island of Ceylon, and so well adapted in every way to the raising of bees, should not yield annuraising of bees, should not yield annually honey and wax to the value of many thousand pounds sterling. In the United States of America, this industry is still in its infancy, improved methods in bee-culture not having obtained in all parts and the "field" not being one-tenth occupied; yet the annual honey and wax product of that country exceeds 1,000,000 pounds sterling, and tons of pure nectar are yearly shipped to Europe, much of it being sold in English markets at 4½d to 6d per lb. One weekly publication and 6 monthly a graduated to bee culture in per lb. One weekly publication and 6 monthlies are devoted to bee-culture in America. Those familiar with the condition of agriculture in Great Britain per lb. and Ireland admit that the industry is sadly neglected, yet movable comb bee hives with improved methods are gain-ing ground, and England has one jouring ground, and England has one journal devoted to the interests of apiarists. Abont a year ago I came to the Island of Cyprus, mainly for the purpose of rearing and sending to European countries and to America queen bees of the highly valuable race found on that island. Among the Greek and Turkish peasants of Cyprus I found a system of bee-keeping which, though far behind the modern approved methods, is still superior to the cruel plan yet followed largely in many of the countries of Europe, notably in France, and even in England, namely: the barbarous practice of brimstoning the bees to obtain their honey. The native bee-owners in Cyprus place the bees in clay cylinger to the countries of the tice of brimstoning the bees to obtain their honey. The native bee-owners in Cyprus place the bees in clay cylinders, some of which are baked, others sun-dried, and these are then piled up and covered with a roof or embedded in the walls of the houses. The cylinders, which are about one yard long and 8 or 10 inches in diameter, have their ends closed by stone disks plastered in with clay, a small entrance hole being left the bees at the front end. When the time for taking the honey arrives the time for taking the honey arrives the peasant bee-keeper removes the rear disk and having smoked the bees from the rear combs, cuts out a portion of the latter, leaving the bees, however, some combs of honey for their subsistence until the next gathering season arrives. According to the books of the Collector of Tithes the number of hives of bees kept in Cyprus in 1878 was 32,432, and the sales of honey and wax was no inconsiderable item to the peasant own-

If that poor barren Island, Cyprus, successfully robbed by various govern-

ers of bees.

ments and rulers, and for more than ments and rulers, and for more than 300 years under Turkish misrule, could constantly derive benefit through the culture of bees, surely Ceylon, under fostering Britain's care, can show a result a hundred-fold greater. That Cyprus in its flourishing days, before it was so nearly stripped of its forests, yielded much better results in this direction is shown by the figures given me by the officer mentioned above, who stated that there formerly existed on the island 200,000 hives of bees. In the scattering of pollen from flower to flower and consequent complete fertilization of the blossoms insuring a larger yield of fruits or seeds, the bees play no unimportant part. Here then is an no unimportant part. Here then is an industry that should go hand in hand with fruit growing, coffee planting, cotton raising, etc., and should add to the wealth of Ceylon by putting into a marketable form the nectar which now wastes its sweetness on the desert

The Dutch Government seeing the advantages likely to accrue through the cultivation of bees in Java, sent to that possession several years ago a native of Holland, commissioning him to transport from Europe colonies of the Italian and Cyprian bees, and to superintend their introduction into that island. If this undertaking had not been successful, it is only because the government referred to was so unfortunate as to have selected for the work a man lacking the necessary practical experience and qualifications. The undertaking, however, has by no means been re-linquished, and I feel safe in predicting that living colonies of the species Apie melifica will soon be landed in Java, having myself brought safely as far as Ceylon, 17 colonies of Cyprian and Holy Land bees, which are to be taken to that island.

For the Island of Ceylon, the rude method of keeping bees practiced in Cyprus and the adjacent Mediterranean Cyprus and the adjacent Mediterranean countries would be preferable to no bee-culture at all, yet as wood here is abundant, hollow logs might be sawed into suitable lengths, a board nailed over the end for a cover, and the hive thus formed placed upon its open end upon a stand a few inches from the ground. An auger hole bored through the board cover would let them enter a box placed over it, and there deposit surplus honey. When filled, or at the end of the honey season, the box can be removed without disturbing the bees removed without disturbing the bees in the body part of the hive. Or, boxes of about 2,000 inches capacity can be treated in the same manner. Hiving the bees simply consists in shaking the cluster from the tree upon which it has cluster from the tree upon which it has lodged into the box, or into a basket, and then pouring it down before the hive. Most of the natives have little fear of bees; moreover, when bees are about to swarm, it is their instinct to gorge themselves with honey and when ther honey-sacs are thus filled, when ther honey-sacs are thus filled, they never sting unless pressed in the hand or under the clothing.

The simple methods indicated above are surely not beyond the comprehension of the natives of Ceylon; indeed, I believe an additional step might be taken at the outset—a step which in the long run would be found wise.

Farm hives—something essential to modern bee-culture—might be intro-

duced into some of the government gardens, and then would find favor elsewhere. Notches in the upper edge of the hive would insure the placing of or the five would insure the placing of the frames at proper distances, one from another, and the main advantages of the movable comb system would be learned by practice in handling the bees. To start this work, the government might manufacture and sell at cost simple movable camb hives parkens simple movable comb hives, perhaps even stocked with bees, and for the present exempt the industry from taxation.

These are the ideas which suggest themselves to the mind of one whose stay in Ceylon must necessarily be very short, but who feels an interest in seeing a favorite pursuit receive the attention its importance demands.

FRANK BENTON.

For the American Bee Journal.

#### How to Feed Bees in Winter.

A. BENEDICT.

A great many bees are lost in April for the want of a little care; young bees are hatching rapidly, consume honey fast and may get out of feed; and they should be watched closely. A little feed may save many that otherwise would perish. If the weather is too cold for the bees to fly, I take the hive into a warm room, remove the cap and place instead a box that will lit tightly, so that the bees cannot escape. This box has neither top nor bottom. On the frames I put a sheet of newspaper, leaving plenty of space for the bees to come up in the box; the paper is to keep the bees from soiling the hive. I place the feed in the box and cover the box with mosquito bar. The hive should be put nosquito bar. The hive should be put by a window to have plenty of light. After the bees have had a good cleans-After the bees have had a good cleansing flight I darken the window and let the room gradually cool, and the bees will go down and cluster. In this way bees can be fed and have a flight in the coldest weather. If the combs are very wet the hive should be put in a dark, dry and cool room, until the combs are dry. A good colony of bees will stand any amount of cold if they are kept dry. The only object for housing bees is to save honey. save honev

Bennington, Ohio.

For the American Bee Journal,

#### Do Bees Puncture Fruit?

DR. WM. R. HOWARD.

To the question "Do bees injure or destroy sound grapes?" I answer no, positively. I have tried the following experiments: Bees were covering the grapes in the vineyard and seemed actually intoxicated on the wine. Removing several bunches, some of which had punctured berries and some sound ones, were taken to the apiary, and the bees soon found them and went to work vigorously. As soon as the punctured ones were exhausted the bees abandoned them and went in quest of something better. Then the bees were furnished better. Then the bees were turnished some of the same lot and closed in the hive; as soon as the punctured ones were exhausted they seemed uneasy, then bunch after bunch of sound grapes were given them, which were eagerly covered, but as soon as it was found that none were punctured they fell back in dismay. Others conducted similar in dislinay. Others conducted similar experiments, and nearly all had the same reports to make. I had one man come to me and tell me that his bees would clean them up all alike, so I went over to his place to conduct the experiment and satisfy myself, and when we arrived, lo! wasps. bees and ants were all promisciously engaged in the feast; so we cleaned up and commenced ancw minding the wasps away for a few hours, and the fruit was abandoned as before, and after being left an hour or more to themselves, again we returned and bees and wasps were promisenously engaged. Wasps were kept away by entomologists' netsto catch them as they came up, and a pair of collector's forceps to pick up those which escaped and alighted. Now for the physiological reasons why bees cannot commit the offenses charged against them.

and on the edges are covered with still finer hair, with a second row around the internal surface just suited to work soft wax and brush it up and give it the proper finish. If anyone will examine these mandibles with a good microscope it will satisfy him at a glance of the incapability of the honey bee to damage, by puncture, any fruits whatever.

Kingston, Texas, March 11, 1881.

For the American Bee Journal.

#### Perforated Zinc to Confine Queens.

D. A. JONES.

Mr. Dadant misconstrued my remarks at the Cincinnati Convention on the above subject. I claimed to have discovered, by the use of a perforated metal division board, that I could take far more comb honey from the body of the bine, not the greatest are more to the proposed of the bine. more comb honey from the body of the hive—not the second story, as 1 use one-story hives. I did not advise two-story hives, for 1 can accomplish better results with a single story. I said some bee-keepers, more especially ministers, wanted to leave their hives on the Sabbath day, and occasionally at other times, and that by lifting the comb with the queen and placing it behind the perforated metal division, they could not swarm, or if they did, they would return to the queen. Queens might be killed in a queen-yard sooner than in a hive; however, I have had none killed in the hive yet, and if I had, I would much rather lose the queen alone than the

queen and swarm, too.

I am very glad Mr. Dadant mentioned his loss of one, and the conclusions he came to in the queen-yard trial. I will test the matter further this year. I am not aware that any person ever tried my not aware that any person ever tried my plan of procuring comb boney in the brood chamber. I have not had enough experience with it to be very positive; but it appears to be all that can be de-sired so far, and I have prepared part of a lengthy article on the matter, which I hope to publish before the honey sea-

Years ago 1 advocated extracted honey, when I had to introduce it on the market, against popular prejudice; not so now. Many who thought comb honey was the most remunerative, are honey was the most remunerative, are now modifying their opinions in favor of the extracted. Now, if my plan of taking comb honey from the brood taking comb honey from the brood chamber works as it did last fall, what won think if you heard of people.

This official recognition of our assomble won think if you heard of people. the thir extracted into comb honey, after the harvest was over, and this within a few days? I have great respect for Mr. Dadant's opinion, and his efforts in marketing extracted honey deserve the thanks of all bee-keepers. Beeton, Ontario, Canada.

For the American Bee Journal.

## Theory and Practice.

L. H. PAMMEL, JR.

Without theory an apiary can never be conducted systematically, nor can any one master the science of bee-keeping without having acquired a theoretical knowledge of how an appary should be conducted. True, men that only had a practical experience have met success, and through their labors bee-keeping has become a science, but their success was acquired through hard and patient toil. Hundreds of bee-keepers have been imprived into the guas of dysennever inquired into the cause of dysentery; nor do they know where wax comes from. Though the production of wax has nothing to do with the management of an apiarry, it is one of the peculiarities of the industrious insect; yet, strictly not an evolution, and made from natural causes no naturalist has from natural causes, no naturalist has as yet been able to say how honey is transformed into wax.

While it is true that all cannot be theorists, it is also true that theory alone cannot, will not, make us successful; but when we put correct theory into

The mandibles of the honey bee are not dentate or serrate, but are simply subject. Our agricultural schools are smooth, and beautifully rounded at the condemned by many, for teaching too ages. Much of it has been thrown on subject. Our agricultural schools are of putting up honey in attractive pack-condemned by many, for teaching too ages. Much of it has been thrown on much science. Such should not be the the market, a wretched conglomerate as a scholar refines his thoughts. There is too much science in agriculture and bee-keeping for mere practice. There is every opportunity tomaster the theory. Our BEEJOURNALIS doing a noble work; so also is such able books as Prof. points, spoon or scoop-shaped, covered much science. Such should not be the on the body with line hairs rather long, as a scholar relines his thoughts. There work; so also is such able books as Prof. Cook's Manual of the Apiary and Quinby's New Bee-Keeping. The beekeeper and the farmer should have the same standing among their fellow-men as the merchant or the lawyer, and to that aim our agricultural colleges are working, and I hope that at a day not far distant they will be attended more. l also hope that our agricultural, horticultural and bee papers will be in larger demand, so that the editors will receive a fair recompense for their labors. LaCrosse, Wis., March 15, 1881.

## Bee Farming in Ontario.

WM. F. CLARKE.

In April last, the Government of Ontario appointed a Commission to investigate the condition and prospects of agriculture in this Province. Their report has been presented to the Legisreport has been presented to the Legis-lature, in the shape of 6 large octavo volumes, comprising about 2.400 pages. The first of these volumes contains the report proper, the remaining 5 be-ing filled with the evidence on which said report is based. A brief extract from the report on bee-keeping, will no doubt interest the readers of the Amer-ican Bee Journal. The Commis-sioners in sumping upon this tonic ICAN BEE JOURNAL. The Commissioners, in summing up on this topic, remark as follows:

"The bee-farming industry, in the

"The bee-farming industry, in the Province of Ontario, had not, until recently, attracted a very large share of attention. For some years, however, it has been carried on by several persons with judgment and intelligence, upon improved methods, and very satisfactory results have attended these efforts. To-day, the Province can probably boast of operations, in connection ably boast of operations, in connection with this industry, as spirited and enterprising as can be found in any part of the world.

The Commissioners have noticed with pleasure the formation of a Bee-keepers' Association, and have no doubt the bee-masters will derive as much ad-

This official recognition of our asso-ciation is replete with encouragement, because it furnishes ground to hope that the government will enrich it with a grant of public money. The Province gives \$1500 a year in aid of our 2 Dairy Associations, and \$750 a year in aid of our Frnit Growers' Association, beour Frint Growers Association, be-sides \$10,000 a year toward the funds of the Provincial Agricultural Associa-tion. As the result of this liberality, the Provincial Application. As the result of this liberality, our Pairy Associations are able to secure the best talent at their annual meetings, which are schools of dairying, holding 3 days. This year, we had Prof. Arnold, Hon X. A. Willard, Prof. Roberts, and Hon. Harris Lewis, veteran teachers of dairy science from the United States; besides our own native dairymen. The Fruit Growers' Association is enabled by means of the government. dairymen. The Fruit Growers' Association is enabled by means of the government bounty, to hold meetings for discussion and instruction twice a year in various parts of the Province, and all these bodies are in a position to dis-seminate reports and other documents full of information, with a liberal band. We hope soon to have our Bee-keepers' Association in a like position, and then our prominent apiarian brethren across the lines may expect cordial invitations to come over and talk to us at our

annual meeting, expenses paid, and something to-boot.

Up to the present time, no large foreign trade has been done in Canadian honey. In 1879 and 1880, Canada exported 7,940 lbs. weight, a small amount is itself, but indicating the commence.

sections of comb honey. There is every prospect of increased attention being paid to bee-keeping, but the country will absorb most of the extra product for some time to come. There is not a town or village where the sales of honey might not be multiplied tenfold, as the result of a better style of bee-keeping. At present, it looks as if the business in this country were capable of indefinite expansion and on the ble of indefinite expansion and on the eve of it.

## The Sale of Extracted Honey.

J. D. KRUSCHKE.

Extracted honey has been offered the consumer in this country for a number of years, but to-day, at the average, the demand is not so great as 5 or 6 years of years, but to-day, at the average, the demand is not so great as 5 or 6 years ago; the cause is undoubtelly adulteration and cheap comb honey. In 1872 I sold the first extracted honey in this town; my trade increased every year, until 1 had the misfortune to lose my bees by foul brood. An absence of 4 years has driven the extracted honey again to the wall. A few objections are ventured by consumers, and these are well censidered by the Messrs. Dadant in their pamphlet on Extracted Honey, which should find its way into every home. Could this be accomplished the industrious bee-keeper would find a better income from his bees, while the idler, who has so much other work to demand his attention, who hardly ever opens a hive, and finds his task mostly completed in putting on and taking off the boxes, would be forced to give up the business, or give it the attention and care he does his cows, sheep, or farm, if he be a farmer. Any one who keeps bees because it affords an easy living, would soon find out the mistake if he undertook to produce extracted honey.

There is no telling how much boney might he consumed if the prevalent

duce extracted honey.

There is no telling how much boney might be consumed if the prevalent idea that it is a luxury which none but the rich can indulge was removed. People will buy A sugar and use it in the most lavish way who probably never taste honey from one year's end to the other, even if the price were equal, simply because they hold it a luxury which their means cannot indulge. Let all the bee-keepers stir themselves, and let the praises of extracted honey be heard throughout the land.

Foul Brood.

w.

My eye caught an article in the Jour-NAL for March 10. by 11. L. Jeffrey, on this subject, in which he appears to dif-fer from all the writers I have read on this important subject; but for 10 years this has been my opinion although I auxiously wished some one would com-mence its discussion, to cause apiarists to think and write about it, and lead to a proper knowledge of tt; but I refrained from writing my sentiments because all who wrote about it seemed to think that foul brood was a disease to which bees were subject, and that the disease was spreading and might exterminate whole apiaries in large localities. The acts of the Michigan Convention is a proof.

Ten years since I had foul brood in

my apiary, which led me to seriously reflect on the nature of the disease, and what would be the cure. I then formed my ideas, which I have had no occasion to alter. At that time one of my colonies especially was so badly affected with foul brood that the effluvia was adone cannot, will not, make us successful; but when we put correct theory into ment of a foreign trade. It would seem that bitherto the home consumption which we may undertake. Failures in bee-keeping and all other pursuits, are

although bees from healthy colonies en although bees from hearthy colonies en-tered to rob it, they certainly were not affected by it; this led me to believe that it was not contagious, but only the effect of want of proper judgment and application. Since that time I have used the means which I then determined on, and have not since seen the disease in my apiary, although I have had 80

olonies at once.

I am willing to give you my further experience on this matter if desired; I do not like to differ from so many able

writers on this subject.

Let all who have suffered from this disease express themselves fully in your excellent BEE JOURNAL, no matter how ever little they write, and let this disease be properly explored.
Ontario, Canada.

(By all means, let us have the facts and experiences. We want "light." -Ep.]

## The Use of Perforated Zinc.

O. O. POPPLETON.

"At the National Convention, in Cininati, Mr. Jones announced that he had made an important discovery. This discovery consists of a sheet of perforated zinc, to prevent the queen from laying in the upper story, or in part of the combs. as well as to hinder the bees from swarming, by preventing the queens from going out of the hives."

The above is an extract from an arti-The above is an extract from an article published on page 67 of the Bee Journal, which forms the text for the balance of the article. I notice that several others have written in the same

strain.

was present at the Cincinnati Convention, was quite near to Mr. Jones when he made the statement referred to above, and also had the advantage of an hour's conversation with him on the day after the Convention adjourned, nearly all of which was on this subject, and it is certainly news to me that he "announced that he had made an important discourse" which made an important discovery, which discovery consists of a sheet of perforated zinc to prevent the queen from laying in the upper story," etc. All that has been written in the BEE Jour-NAL to prove that he is not the first inventor of using perforated zinc, is simply so much trouble thrown away, as he

ply so much trouble thrown away, as he very distinctly stated that fact himself. What Mr. Jones did claim was that he "had discovered a new method of using perforated zinc in a hive, so as to have the honey stored in sections in the centre of the hives instead of at the sides or on top." He remarked that he "first experimented with zinc with round perforations but this "?" sides or on top." He remarked that he "first experimented with zinc with round perforations, but this did not work on account of the pollen being scraped off the bees legs as they passed through, but that while in Europe he noticed that bee-keepers there were using zinc with oblong perforations, the use of which remedied the objection to the use of round perforations.

It will be seen by this that Mr. Jones very plainly said that he first found the perforated zinc such as he uses, in Europe, being essentially the same statement that Mr. Dadant, in the article

ment that Mr. Dadant, in the article referred to, attempts to prove.

Mr. Jones said nothing whatever about preventing the queens from laying in the upper story, as the special advantage of his method was to have the honey stored in the lower, and in fact, only story in the hive.

The statement that this device con-

The statement that this device can be used to prevent swarming is eer-tainly a legitimate one for criticism, but I see that the reporter, in condens-

Ventura Co., Cal., Convention.

The Ventura Co. Bee-keepers' ciation held their regular quarterly meeting in Santa Paula, Feb. 5, Vice-President Keene in the chair. best and most economical way of can-ning honey for market.

Mr. Wilkin was called upon to give his views on small packages, as he had had considerable experience in that line the past season. He said that he had sold honey in Ventura, in small cans of died of cold. and netted one cent per pound more than that in large cans. He also stated that in the foreign markets honey was retailed in very small quantities, and that a great deal of our honey was re-canned for that purpose, and he there-fore thought it best to can it in small

cans at once. Mr. Hund stated that a firm in New York had informed him that honey put up in 12 lb, tins would sell in that market as a retail package, and at a higher figure than in anything larger, and for the general trade he preferred them

to anything smaller, and thought he should use them the coming season.

Mr. Wilkin stated that he had an order from England for a large lot of

honey in that shape.

Messrs. Corey, Keene and others spoke in favor of small packages.

The convention adjourned after adoptand others

ng the following preamble and resolu-

Whereas. The bulk of our honey is recanned before it goes to the consumer, at a loss of first package and at a greater expense than we could do it at home, owing to the difficulty of getting it out of the cans, especially when candied (thus making a discount on candied honey) and other disadvantages, besides laying it liable to adulteration by unscrupulous dealers. Therefore he it

Resolved, By this association, that we recommend bee-keepers to—as much as possible—put their honey up in retail packages, such as 2 lb. tins full weight, and 12 lb. or gallon cans—the latter more especially preferred at present.

R. Touchton, Sec. Santa Paula, Cal.

#### Lancaster Co., Pa., Convention.

A meeting of the bee-keepers of Lancaster Co., Pa., was held on March 14, in Lancaster, Pa.

The meeting was called to order by the President, Mr. Peter S. Reist. The following members were present: Peter S. Reist Litiz: I. E. Horshey Mt. Lov. S. Reist, Litiz; J. F. Hershey, Mt. Joy; Elias Hershey, Paradise; John S. Rohrer, city; Levi S. Reist, Oregon. Peter S. Reist reported that out of about 60 colonies, which he bad on the summer stands, he lost about 5 during the winter. Le did not think any of

the winter, 11e did not think any of them froze; several starved. The last time he saw them they were flying and appeared to be in good condition. He put a wind break on the back part of put a wind break on the back part the hives, but the fronts were open,

the hives, but the fronts were open, the same as in summer. He did not feed any during the winter.

John S. Rohrer said he had 6 colonies of bees; wintered them on the summer stands. About the 1st of November he cleaned the hives on top, and then closed them up with the exception of \( \frac{1}{2} \) of an inch. When the warm weather game his bees begin to fly out. He

into a bee-house. He divided a great many, and had lost so far 3 small colonies; the rest are in good condition, although not very strong in bees. In February he took them all out, and found many of them to have young bees. He then put them back again and they are in the house now, although he expects to take them out as soon as the weather gets warmer.

W. B. Detwiler, of Mt. Joy, put into the same style of winter quarters, 80 colonies, and had not lost one. H. H. Myers, of Spring Garden, put

into winter quarters 12 or 15 colonies of natives; and they were doing well. These bees were wintered in houses also. He found that those who left the

bees unprotected had lost a great many.

Elias Hershey put into winter quarters 29 colonies, 9 of which died, and the rest are very weak. He heard from his neighbors, that a great many of theirs had died. He left his bees on the theirs had died. He left his bees on the summer stands. His father, Jacob Hershey, had 10 colonies of natives; they were all well and hearty. Most of his bees had died of dysentery or diarrhea, not of starvation; some of them

Mr. Differndeffer, called the attention of the society to the fact that the dan-

of the society to the fact that the danger was not yet over. A great many of the colonics were weak, and he desired to know how they could be built up.

Mr. J. F. Hershev said the proper way was to take all the combs from them except just as many as they could conveniently cover. They should be well fed and carefully attended in regard to warmth; they should also be kept quiet. They should not be allowed to fly out very much in the spring, beto fly out very much in the spring, because a great many would get chilled cause a great many would get chilled and drop down. As soon as they are getting a little stronger, another comb should be given them, and in that way continue until you have a full-sized colony again. There are a great many of what are called weak colonies that can be kept alive, if they are attended to properly, but if left to themselves, they will surely die. The strong ones must also be carefully looked after. Everything should be kept clean and sweet about the hive, and the hives should be guarded against the cold air.

should be guarded against the cold air. Levi S. Reist had on the summer stands, 3 colonies, and lost one. The other 2 are doing well. The one that died had not honey enough to carry it through the winter, and starved.

Adjourned to meet on the 2d Monday in May.

Read before the N. E. Convention.

#### The Great Revolution.

#### A. WEBSTER.

Are we on the eve of a great revolution in bee-keeping? Indications are that old things are passing away and all things are becoming new. Shall we not say rather that we are in the midst of a revolution that commenced with the invention of movable combs, has progressed through several stages and has not yet culminated? What then, is now wanted to complete this revolution and that are now in use in our harmonious system that shall be so nearly perfect as to win general approval and adoption? combine all the various improvements

I have given this subject long and I have given this subject long and careful consideration, and have been forced to the conclusion that it is a bee hive all parts of which shall be constructed and combined in strict accordance with the laws that govern the working instincts of the honey bee, and that shall harmonize those instincts with the convenience and wishes of the honey tainly a legitimate one for criticism, same as in summer. He did not feed but I see that the reporter, in condensing Mr. Jones' remarks, was necessarily obliged to give this part of them more prominence than I think Mr. J. intended them to have. My recollection is that this part of his remarks was thrown in more as a suggestion than a fact.

I hope this article will prevent other writers from making the mistake of charging Mr. Jones with making the statement that he had first discovered them see of perforated zinc, or recommending it to prevent queens from going into upper stories, etc.

Williamstown, Iowa. March 18, 1881. the convenience and wishes of the bee-

looked? Not entirely overlooked perhaps, for one inventor seems to hav inkling of the true mutual relations of the store and brood combs. He has adopted an original system, which is thought by some to promise grand results, but is not beyond criticism, and it is feared by others that an unfortu-nate choice of forms and combinations will in a measure, at least, countervail the advantages claimed.

And now naving intimated that the mutual relations of the brood and store combs are the vital points in bee-hive construction that needs development, construction that needs development, let me produce practical questions for discussion in this convention, and by bee-keepers generally. Questions of more vital importance than appears at first view, and that must be settled by mutual agreement among bee-keepers. before a universal bee hive and system of management, and a uniform honey ox or set of boxes is possible. What is the best thickness of space

give to each brood comb, in hives to give to each prood comp, in fives where foundation is used and drone rearing entirely exhausted? And what is the best thickness of space to give each store comb, either in sections for comb honey or frames for extracting or feeding that the same hive may be equally well adopted for either pur-

Now in considering this question let Now in considering this question for us first of all inquire of those great mas-ters of apicultural science, the honey bees, how they would answer them, if their purposes required a separation of the brood and store combs, as the bee-keepers do. Fortunately this answer is not hard to find nor difficult to unis not hard to find nor difficult to understand. If we examine a box hive or bee-gum filled with combs by a strong colony during an abundant yield of honey, we shall find worker and drone combs in about equal numbers. We shall also find 8 combs to the foot—2 combs to 3 inches of space. When in use for breeding, the worker combs are \(^{7}\_{8}\) of an inch thick and the drone combs \(^{1}\_{4}\). Now 7 and 10 have about the same ratio that the sides of a square has to its diagonal. Apportioning the space in a 12 inch hive in the same way gives \(^{1}\_{4}\) inches for each worker comb, and \(^{1}\_{4}\) inches for each drone comb. Therefore if we till the breeding depart-Therefore if we fill the breeding department of our hive with worker combs, giving each 114 inches of space and the giving each 1¼ inches of space and the storing department drone combs, giving each 1¾ inches of space, will it not be about right? Such seems to be the opinion of the bees, in which your essayist coincides.

This arrangement will give brood combs of sealed honey about 1½ inches thick and store combs 15%, or 1½ inches thick if separators are used. Applying the same ratio to combs of greater thick.

the same ratio to combs of greater thickness. we find that brood and store combs correspond to each other as fol-

lows, viz:

l hope that these questions will be thoroughly discussed from every point of view, and an agreement arrived at if possible. Whatever it may be, I have no doubt that the bees will accept it gladly if suitable frames and foundations are furnished them. And for myself as an individual bee-keeper, I am willing to yield my opinions for the sake of uniformity. It would be better in this matter to be nearly right in harmony with the fraternity, than exactly right alone.

Bee-Keepers' Union, to be held at Hastings, Minn., May 17, 1881:

## THOMAS C. NEWMAN.

EDITOR AND PROPRIETOR,

CIIICAGO, ILL., MAR. 30, 1881.

### Repairing Losses by Dividing.

1 began the last season with 10 colonies—8 blacks and 2 Italians—and lost all this winter but the Italians, which are strong and in good condition. I never read a bee book, nor saw the BEE JOURNAL till last fall. Had I subscribed for the BEE JOURNAL a year sooner, it would have saved me \$40. I thought I had a good start last summer in the business with 10 colonies, but now I have only 2. Can I build up these two, and ever hope to succeed? Will a good manual help me? What can I do with ever nope to summanual help me? What can I do with 50 or 60 frames of honey on which the S. F. MILLER. N. Manchester, Ind., March 12, 1881.

A seeming misfortune is sometimes a blessing in disguise, and we doubt not, with your spirit of inquiry and the experience of the past winter, you will so prove it. You have every facility for building up, and with the aid of a good manual and the hives and combs of honey left over from the wreek, it will be a work of interest and a profitable experience to replace your losses. Your untenanted hives we suppose to be exact duplicates of those now occupied by the Italians; if not, now is the time to overhaul them, as you should have but one style of hive. As soon as settled weather comes on, when fruit trees are in bloom and the air is redolent with the perfume of spring flowers, you can commence your work of dividing for increase, as follows: Remove your best colony to the stand where a new colony is to remain and place in its stead an empty hive, from the hive removed lift the frame on which you find the queen, and place with the queen in the empty hive on the old stand, now take another frame with sealed brood from the hive removed and place alongside the frame with the queen; close the remaining frames together in the hive from which the queen was removed, and put one of your old combs on each outer side, and you are done with the interior of this hive for ten days. Now, from your other colony (which you will leave on its old stand) remove three combs of sealed J. H. Nellis, Canajoharie, N. Y. brood, shake off the bees, and place in the new hive with the queen; close the combs together, put one old comb on one side and two on the other, close the hive, and you are through with that for the present. The five combs with brood, In the new hive, place in the center, fill complement, and your first division is completed. On the 10th day, remove both hives containing queens, and put empty hives where they stood; now from the queenless colony remove two frames each containing a queen-cell, and place one in each empty hive (if three frames cannot be found containing good cells. graft them in as directed in Cook's Manual, page 167) leaving one in the hive brood (one from each colony removed). give you five hives, two containing five lays have been caused by the storms.

frames of brood and queen cells, two with five frames of brood and queens, and one with eight frames of brood and; queen cell. To the first four, place two old combs, one each side and put in a division board. Every three days add an old comb till full. If the month of May is warm and pleasant, and increase is the main object, you can divide again the first of June. About May 20, remove the queen from your best colony with the frame she is occupying, put her in an empty hive, then add two frames from each of the four with queens; now fill up each hive with old combs, and you have six hives occupied. Nine days after, or when the cells in the queenless colony are ripened, remove the five with queens, and start five new ones where they stood, by taking five frames of brood from each, grafting a good queen cell into each, and filling all up with combs or good foundation. During white clover bloom the colonies will build up very rapidly. In the absence of clean, bright combs, use good foundation, and supply it no faster than the bees can draw it out.

In all manipulations of this kind, do nothing without ascertaining first the whereabouts of the queen; with good Italians this is not difficult, and a slight oversight might be disastrous. Do not spread brood too rapidly, for if chilled disease may follow. Do not begin stimulating too soon: 10,000 bees and eight frames of sealed brood, on the 15th of May, in this latitude, will give better returns than 50,000 bees on April 1st, and a cessation of brood-rearing during the latter part of April and the month of May. We can see no economy in building up strong colonies very early, only to feed through the bleak weather, and die with age just when wanted most. With judicious dividing, and a late fall bloom, considerable surplus may be obtained, but very little early surplus, unless basswood is profuse, or sweet clover very abundant.

Mr. T. F. Bingham has removed to Abronia, Allegan Co., Mich., where his apiary is and has been located for years. Any letters, however, sent to Otsego will reach him, as it is only a few miles from Abronia.

🔯 We have received a copy of " The Domestic Advertiser," a compendium of household receipts, published by Mr. 30 pages are full of good receipts of all kinds, and it will be valuable to every housewife.

Our correspondents have been so liberal with their communications that we have found it necessary to condense, up the hive with old combs to its full and give them much of the room usually devoted to other departments.

This number of the BEE JOUR-NAL will be found intensely interesting. If embraces nearly every topic in beekeeping, and contains news from all parts of the globe. During the storms of the last few months we have received many letters complaining of greatirregularities and delays in the receipt of where found, and put in two frames of their paper. While these complaints are a gratifying proof of the interest This makes your queenless colony full. with which the Bee Journal is re-From the colonies with queens, remove ceived, we regret their occurrence, and four frames each and place in new hives, assure our readers that the paper has each four on their old stand. This will always been mailed promptly. The de-

LONDON JOURNAL OF HORT.

Bees in New Zealand .- The following article from the New Zealand Herald, we find in the above excellent paper :

Among the many varieties of the honey bee few are held in greater esteem honey bee few are held in greater esteen than the Italian variety, or, as it is gen-erally called, the Ligurian bee. They are industrious workers, and delight in honey-gathering. In their hives there are fewer drones than in the hives of the common honey bee, and the queen pro-duces eggs all the year round, though the number is considerably fewer in the winter season than during the warm winter season than during the warm days of summer. About the time of the American Centennial Exhibition, several attempts were made by several attempts were made by Mr. Thomas Russell to introduce them to the province of Auckland, through agents he employed in San Francisco. The first efforts were made by sending queen bees, but the inmates of the several parcels of those that were forwarded all parighed before reaching their destiall perished before reaching their destination. As a last effort a hive was sent forward, but it was evident that there was something still to learn to secure the safe transportation of these bees long distances, for they were nearly all lead before reaching Auckland, and he few sickly ones that reached here dead before reaching died a few days after being landed. The expense of these efforts was borne solely by Mr. Russell. Norwere Mr. Russell's failures to introduce these bees singular, for Mr. A. McKay, of Brisbane, who made efforts to the same end. at the same time was equally unsuccessful to enrich his adopted land

But while the suggestion was made to the Colonial Industries Commission to spend £500 of public money to send a erson home to make an attempt to that in which so many failures had already been recorded, private and patriotic enterprise was successfully accomplishing that for which State aid was being solicited. Mr. S. C. Farr, Secre-tary of the Canterbury Acclimatization Society, had already communicated with R. J. Creighton, formerly of Auckland, and now in San Francisco, on the subject, and Mr. J. H. Harrison, of Coroprecedure of Coromander, and Mr. 3. 11. Harrison, of Coromander, had also communicated with his brother, Mr. W. G. Harrison, San Francisco, formerly of Auckland, for the same object. As Mr. Creighton is regarded as the official representative of New Zealand in the City of the Golden Cate, both amplications came to be re-Gate, both applications came to be re-He made his arrangements accordingly, and the success that has attended them deserves public recognition on behalf of the colony. Mr. reighton regarded these efforts at acelimatization as public enterprises, and not efforts for private gain, and acted accordingly. Hives were made upon a accordingly. Hives were made upon a new construction, and a place provided in which was kept a wet sponge, which appears to have secured that cool and moist atmosphere necessary for bees, so that when they arrived they were as lively as possible, and seemed to be in vast numbers.

The two boxes were sent through the

Acclimatization Society, and entrusted to the care of Capt. Cargill, at San Francisco, who took them into his own cabin. and daily attended to the wants of his lively colonists. Fresh water was daily supplied to the sponges, and everything done that was requisite to the health and comfort of the bees. The result is an unmistakable success, and the colonists in New Zealand are deeply indebted to Capt, Cargill and Mr. Creighton for what has been accomplished. Mr. Creighton, has been accomplished. Mr. Creighton, in his letter to Mr. Cheesman, the Secretary of the Acclimatization Society, states that Mr. Harrison is not to regard his hive as an object for private profit, but the bees are for the good of the colony, and when swarms are obtained they are to be distributed in the same way that he has been provided with them.

Canterbury, New Zealand, care of Mr. Creighton, San Francisco. These bees were received in New Zealand in good condition, considering the length of time in transit, and the hazardous portion of the trip from Chicago to San Francisco by rail. They were in a tenframe Langstroth hive; his manner of preparing them was described in the BEE JOURNAL of Jan. 5, 1881. Mr. Wilson, in a letter to the editor of this paper, written in January, says this colony has been increased by the dividing process to four good colonies.

Mr. A. H. Newman informs us he has booked an order for several colonies this spring for Mr. A.V. Maedonald, Parnell, Auckland, New Zealand. We are in receipt of the following letter, dated Jan. 3, 1881:

...I have heard a statement made that the Ligurian bees, when they have not been obtaining flowers requiring the use of the long proboscis, gradually lose the length, and with the shorter tongue do not gather from red clover. As some colonies have already been obtained from the United States, it would be well to settle the point, Do Ligurian bees successfully fertilize red clover? I lately had a small swarm sent me from the country, minus the queen. I let them remain all night in the hive I had transferred them to, and in the morning shook them out, very weak and doleful, snook them out, very weak and doleft, in front of a strong colony in full work, but a little on one side of the entrance, and left them to their fate. Half an hour afterwards I found them all on the alighting-board fraternized, the bees of the hive pushing through the throng with pollen, and others starting out without molesting them. I presume that the hive bees being very busy, and the queenless bees going quietly to the entrance, had not excited suspicion, and thereby obtained the same scent and were accepted. In this latitude we have were accepted. In this latitude we have no trouble with wintering bees so far as cold is concerned, but colonies are much weakened by working in winter when we have constant squalls of rain, which must destroy numbers.

A. V. MACDONALD.

At times when there is a scarcity of other nectar-yielding bloom, we have observed great numbers of Ligurian or Italian bees working on red clover; but only at such times. We do not believe it is a favorife with any honey bees, and is only utilized as a dernier resort, as are several other honey plants. That there is any permanent contraction or expansion of tongue is not true. though it might be possible to develop or obliterate physical traits by careful or negligent breeding.

Care of Weak Colonies. - Mr. F. L. Dougherty, in the Indiana Farmer. gives the following advice:

Many colonies that have passed the severe winter have come through in a very weak condition and will require careful handling to build them up into good colonies, ready for the honey yield when it comes. Weak feeding should be done inside the hive if possible. It is not necessary to make syrup with which to feed at this season, sweetened water is just as good, two parts sugar and one of water. The quantity to feed should depend on the strength of the colony, and should be placed as conveniently as possible to the brood cluster. If it can be given to them warm, so much the better. We know of nothing that will operate as effectually against spring dwindling as feeding this thin syrup. It gives the bees food and water. syrup. It gives the bees food and water, and this with sufficient heat, stimulates to brood rearing. Their instinct inclines them to cluster in the brood nest to keep up the necessary heat to accomkeep up the necessary near to accomplish this desirable result; and as they have both food and water inside the hive, and work to accomplish also. In August last Mr. A. H. Newman, of Chicago, shipped a full colony of bees to Mr. Thomas Wilson, at Kaipoi,

# SELECTIONS FROM

The Lime Remedy,—Clark county contains many practicable and enthusiastic bee-keepers. We are not all discouraged, as we have a few left yet. Such losses were never witnessed by such losses were never witnessed by the oldest inhabitants in this part of the country; one person had 40 colonies in a bee-house, all are now dead. Another had 32 on the summer stands; all gone but one; another had 60, half in cellar, half out doors; all are gone but 8; those in cellar did no better than those out doors. Another had 12; all gone. Another had 4; 2 are left. Another had 125, lost over 12, 3 weeks ago. One had 9 and lost one. Another had 5 and had 9 and lost one. Another had 5 and all are dead. I lost 4 out of 10, in double-walled Langstroth hives except double-waned Langstrott investexcept 3 colonies, which are now dead. I took to the lime project "like a duck to the water" and have used lime in 3 colonies and they are as strong as bees usually are in the middle of April. I like the Weekly BEE JOURNAL Very much.

J. C. OLDHAM. OLDHAM. Springfield, O., March 19, 1881.

Bee-Keeping in Kansas,—1 bought 2 colonies last June, but did not get them home, until July 5; they gathered enough honey for winter but no surplus. I am wintering them on the summer stands in Langstroth hives, with chaff cushion over the frames and an outer case, but not packing between the case and hive. They are wintering nicely, but had no flight all winter. Early plants are getting green, but we have had the hardest winter ever known here; twice the mercury was 18° below There are not many zero at sunrise. bees in this vicinity and what are here are poorly cared for, and some have died, as they have to go through the Will Emerwinter the best they can. son's binder hold more than one volume of the Weekly Journal? I wish the Journal all prosperity. It is a wel-JOURNAL all prosperity. It is a we come visitor. S. C. FREDERICK.

The binder will hold but one year's numbers. They can be removed and and bound, and the binder used for years.—ED.]

Chaff Packing. - I have set some grape vines out in my bee yard and would like to put sawdust in if it will not hurt Journal. Bee-keeping was a failure last season: the bees obtained no honey from white clover, and not much from linden. The most honey I got was through August. I had 12 colonies last spring and got about 125 lbs. of surplus honey, all extracted. Increased to 22 and lost 5 through this cold weather. I now have 17 in the cellar. I put them in the cellar Dec. 10. They are doing well so far. I wish success to all the They are doing bee-keepers and the BEE JOURNAL. Weekly the best of all. It is cheap at \$2 a year.

Salamonia, Ind. take 4 is cheap at \$2 a year.

[Keep the sawdust away from the roots of the grape vines.—ED.]

Wintered Safely by Chaff.-My bees gave but little surplus honey last sea-son. I commenced the season with IS colonies and increased to 34 by natural swarming. I never saw bees breed up swarming. I never saw bees breed up so strong in numbers, and most of the hives were literally crowded. went into winter quarters very strong and nearly all with plenty of honey, but our winter has been so severe and long that I feared for them. They had no that I feared for them. They I flight until late in Feb., when I they had dysentery. I examined them to-day. One froze just before New Years and one I found dead with empty combs; both were weak in the fall. I found one just out of honey and gave them some; the rest are strong in numbers and have plenty of honey. So I have saved 32 out of 34, which I call pretty good. I wintered on summer pretty good. I wintered on summer stands with chaff cushions on top, and entrance closed to about 2 inches. Sev-

enty-five per cent, of the bees in this vicinity are dead; many have lost all. I think the Weekly BEE JOURNAL is a great advance. Success to it,

A. D. STOCKING. Ligonier, Ind., March 18, 1881.

Bees Strong and Healthy .-- The reoorts from this section are: some have ost all their bees, some a part, and others report that their bees have wintered I placed 68 colonies in the cellar on Nov. 18, and put them out on March The thermometer was at 45, it be-16. The thermones.

Ing the first suitable day. They came out strong and healthy. My loss so far is one colony.

C. H. France. is one colony. C. H. Erie, Pa., March 20, 1881.

Absorbents.—My bees are nearly all dead, but I can not give it up yet. I expect that some absorbent, such quick-lime or sulphuric acid, would such as quick-lime or sulphuric acid, wall-of great advantage in wintering. Th BEE JOURNAL is a pleasure to me. S. P. Hyde.

St. Joseph, Mo., March 16, 1881.

No Surplus nor Increase.—Bees fared badly in this section last year; there was no surplus nor swarms. I started in the spring with 20 good colonies; 4 having lost their queens I united them with others. I put 15 in the cellar in with others. I put 15 in the cenar in the fall; 2 perished, one was weak and died after taking them out. I left one out-of-doors in a double Langstroth hive, but it perished before winter was half over; the rest were in American hives. I have a double cellar, and put them into the outside one; it was too damp, and was kept about the freezing point. I put them in Nov. 15, and they did not get a tlight until March 2: they have had several flights since. The bees in this part of the country have mostly perished. I sowed buckwheat, and last fall my bees obtained honey from it; I also sowed some alsike clover last spring; it took well and stood the hast spring; it work not clover. I am winter better than red clover. I am pleased with the Weekly Ber Jour-Nal.

S. H. Ruehlen. AL. S. H Ru Jerome, O., March 21, 1881.

Bees in Nebraska.-The past winter has been the severest we have had for 20 years. Snow still covers the prairie, one foot and a half deep. We cannot rely for honey on the natural produc-tion of our prairies; we must sow if we propose to reap. Our colonies are composed of Italians and the black bees; the Italians, of course, being our favorites. The black bee is a good honey gatherer, but as mean as it can be for stinging. Out of 54 colonies we have lost 8 up to the present time; some from starvation and others from dysentery; if they had not died from dysentery they probably would have starved. The incold weather continually from the beginning of winter until spring, did not allow them to move from one could not reach their stores. I am speaking of those wintered out-doors, and not properly prepared, as was pretty and not properly prepared, as was preceding enerally the case here this winter. Our bees have mustard plant, clover, fruit blossoms, golden rod, buckwheat, and what they could get from other small blossoms that abound in the prairies.

The prophecy that the year 1881 will be The prophecy that the year ISSI will be a good honey year makes the heart of the apiarist glad, for well he deserves a bountiful year. One man lost 60 out of 75; this is the greatest loss that we know of in this county. We hail the Weekly BEE JOURNAL with delight, and think that all interested in apiculthe best bee-paper in America. Is the Langstroth hive still covered with a patent?

LEOPOLD MOLLER.
Fremont, Neb., March 22, 1881.

[There is no patent on the Langstroth hive now.—ED.]

Bees Starving in the Cellar.—Last evening I examined my bees in the cellar and found 8 dead, and others in a starying condition. I bought all the cream caudy in the stores and sent for more. It is better for cellar feeding than syrup. Their condition takes me by surprise, as they were heavy last fall. J. E. Capy. Medford, Minn., March 24, 1881.

Doyetailed Sections.—I will say to Mr. Lewis, that I was not comparing his dovetail work with his one-piece section. The advantage in a section that will stand firm at any angle, is that four of them but together will make a matched square, proving them to be square; can you make four solid blocks that will do it? Will some solid blocks that will do square, proving them to be square: Will one-piece sections do it, unless strained? As long as bees use glue (propolis) we need close joints to work rapidly and with comfort.

JAMES HEDDON. Dowagiae, Mich., March 23, 1881.

Sundry Questions.—I was delighted with the Monthly BEE JOURNAL, but the Weekly is far more beneficial. It seemed so long to wait from one month another, and even now I eagerly grasp the Weekly as soon as it comes, in the expectation of receiving something new every week. Last fall I had two colonies, but one of them is now dead. How can I clear the combs of dead bees? Will the combs do to put another colony into? My colonies had plenty of honey last fall. I often see it advised to put the hives within a few inches of the the hives within a few inches of the ground, but when a swarm gets away (as one of mine did) they often get into a hollow tree, a good height from the ground—Do they not in this act out their mstinct? The one I lost went towards the "bush," not far away. This winter 2 men found a swarm in a tree, in that "bush," they cut it down and obtained bush;" they cut it down and ordinate 2 pails of honey from it. I suppose them to have been my bees. It is said that bees never do well on the north side sheet of water. I am situated north of Lake Simcoe, and if that is true I shall not succeed. Is that theory correct? MOORE.

Barrie, Ont., March 14, 1881.

[Your first question is answered in the Weekly BEE JOURNAL of the 16th inst. To the second we answer, yes. The instinct governing a swarm of bees prompts them to fly up to the opening in a tree, so long as the opening will not come down to them. As a rule, bees do not thrive so well on the north side of large sheets of water. We suppose it is attributable to the fact that the heaviest honey flows are during the prevalence of the sultry southern winds of summer, enabling the bees to fly to the honey source direct from the hives, by following up the scent. If on the north side, the bees have to search for the nectar from the time they leave the hive, and face the wind when returning heavy ładen.—Ep.1

Bees Short of Stores. - Many bees have died here this winter, from being unprotected from the cold and being short Ira Dăvis. Glass River, Mich., March 22, 1881.

tiood Results. — I commenced the spring of 1879 with 6 colonies, increased to 13 and had 400 lbs. of comb honey; I wintered all safely in the cellar and on the summer stands, packed with chaff. Last year I had 31 colonies and obtained 1000 lbs of comb honey, and left the colonies 30 lbs. apiece to winteron. Thanks to the Bee Journal and Cook's" Manual," I have lost no bees. I should be ual," I have lost no bees. I should be lost without the BEE JOURNAL.

H. A. SWIFT. Eaton Rapids, Mich.

Bees in good Condition. -- Bees have suffered much this winter. Some bee-keepers have lost all; others ½ to ½. All but me are using box hives. I started in the spring of 1880 with 8 colonies, and obtained 800 lbs. of comb honey and 165 lbs. of extracted, besides increasing to 20. I wintered on the summer stands, in a close shed, open to the south; I packed straw around the hives, and fine-cut straw in the caps, about 5 inches thick. I had 3 sticks under the quilt. I examined them on Jan. 29, and found them strong and heavy; most of them have brood. I think they will come out in good condition in the spring. I like the Weekly very much; it was too long to wait for the Monthly. Wisner, Mich. J. P. Phelps, Jr.

the storm in November I put 63 colonies my cellar; most of them in the with no signs of dysentery. Last summer 1 had 5 or 6 swarms, which I returned to the parent hive after cutting out the queen cells. Every 5 or 6 days they would swarm out without any queen cell in the hive. They did that 5 or 6 times each; I put them back each time, and they gathered a fair surplus of honey. What was the cause of such action? L. W. HARMON.

S. Yorkshire, N. Y.. March 17, 1881. [They were badly imbued with the

Life in the Midst of Death. - All around

me bees have died. Many have lost all; others, one-half or two-thirds. After

swarming fever, which sometimes is as unaccountable as are some cases of abnormal swarming.—Ed.1

Equal Loss In-Doors and Out.-The past winter has been a very hard one on bees, and our losses will come very near 25 per cent. However, we have enough left for seed, and will show them how quickly we can recover our losses. The percentage of losses is about equal in-doors and out. It seems useless to spec-ulate as to causes—we might as well lay it to the winter as anything. "Facts it to the winter as anything. Facts are stubborn things," and theories—well, the bee-keeper that is not chock full of theory is either a very matter-of-fact person, or has not read the papers. I was among the number who pers. I was among the number who felt very reluctant to part with the old AMERICAN BEE JOURNAL, but I must confess the new is so far superior. I am glad the change is made, and wish yo all success.

C. S. Burt. Brecksville, O., March 21, 1881.

Why the Wire-Cloth Inside ?-Our bees are happy—no losses worth mentioning. In the issue of March 9th, page 78, 4th column, in answer to W. R. Young, in speaking of boring the inch auger-hole in each end of the hive, why is the wirecloth necessary, if the holes can be plugged when not needed? I should with my experience, for I use them, not put wire-cloth over the holes. I am thankful for the Weekly—it is good.
R. C. TAYLOR.

Wilmington, N. C., March 16, 1881.

[During the hottest weather we frequently have cool nights, caused by excessive dews, when spiders and other insects take advantage of these holes to effect an entrance to the inside of the hive because of the heat; again, the moths gain easy access to the combs through these holes if not protected by wire-cloth, as they are never so well guarded by the bees as the entrances. -En.J

Fresh and Frequent News.—I commenced last season with 19 colonies in Langstroth hives and increased to 28 by natural swarming. The season was natural swarming. The season was very poor here; there was plenty of bloom but it seemed to contain no necbloom but it seemed to contain no nectar. I obtained about 50 lbs. of comb honey but no extracted. I had to feed considerable in the fall. Winter commenced so early that I was unprepared. I packed IS colonies in chaff; the rest were unprotected, and I express it mildly when I say that I was uneasy about them. Feb. 26 was a warm day, and the bees had their first really good. about them. Feb. 26 was a warm and the bees had their first really had been now. I improve flight since last Nov. I improved the opportunity to examine them and found 7 dead, 3 very weak, and the rest in fair condition; 4 of those dead were packed. 3 unprotected. It has been a hard winter on bees here, and winter is not over yet. Comb honey is all that is in demand here, but I intend to create a demand for extracted, if any Italians are left to gather it. I hope the Journal will keep on agitating the adulteration queskeep on agitating the adulteration question until there is something done. It is needless to say that I am pleased with the Weekly, it is so nice to get it fresh every week. I never lay it down until I have read it through.

N. W. WILLIAMS.
North Uniontown, O., Feb. 28., 1881.

A Word to Bee-Keepers.—Snow to the tops of the bives, but the "blizzard" has moved on, or else the snow business has "played out," after falling continuously for 33 hours. We have lost bees from the middle of February until date, and will not be able to ascertain how many until the snow leaves. We had a many until the snow leaves. We had a few mild days which we improved doubling up weak colonies. As soon as the weather is suitable, we shall try to make every bee do its very best—every one must count. We do not consider the old winter our worst enemy, however, but glucose. It has deprived bee-keepers of more money than anything else; especially that mixture labeled "Vermont maple syrup." The honey crop especially that mixture labeled "Vermont maple syrup." The honey croplast season was below an average, yet "honey is of slow sale." Can it be possible that the purest sweet under the heavens goes begging for a market, while millions of gallons of starch, impregnated with sulphuric and nitric acids, and sweetened with New Orleans molasses, finds ready sale? Bee papers are read principally by bee-keepers, who are all posted with reference to glucose. are all posted with reference to glucose, but the outside world is not. Beekeepers, one and all, buckle on your armor, and endeavor to inform the masses what pure honey is, both by talking and writing for local papers everywhere. In this way, and in no other, can they be informed. Mrs. 12. HARRISON. Peoria, 111., March 21, 1881.

[Mrs. Harrison has struck the keynote in solving the whole problem; the people must be awakened to the frauds being practiced upon them, then with hours. an irresistible impulse they will demand laws at the hands of Congress to stop the outrages. Meantime, we know of no one who wields an abler pen than does Mrs. Harrison, nor a better field for its local use than hers, with its score of papers.—ED.]

Foul Brood and its Causes. Foul Brood and its Causes.—I have for years been of the opinion that beekeepers generally were mistaken as to the cause of foul brood. I have just read an article in the Weekly Bee Journal, by Il. L. Jeffrey, of Woodbury, Conn., that expresses my views on that subject so fully, that I want to call the attention of the fraternity to it. Believing as I do, that the practical suggestions he has made are of the utmost importance, and if heeded, we will hear but few, if any complaints in the future, about "foul broad." Read this article, it is found in the few the second of the sec article; it is found on the 1st page of the number for March 16.

I. P. Wilson.

Burlington, Iowa, March 18, 1881.

Red Clover Italians, -I inclose the Ref Clover Hamans.—I merose the subscription for my welcome weekly visitor—the American Bee Journal.

My bees are in good condition.—I fed them plenty of coffee A sugar syrup, last fall, and then put them up in chaff. ast rail, and then put them up in chail. I only lost one colony, which was shaded with a large arba vita tree about 3 o'clock in the afternoon. This weakened the colony. My bees are all Italians. I have purchased queens from different breeders, but my best colonies are breed from queens obtained from my are bred from queens obtained from my neighbor, Mr. J. A. Bucklew; they were bred from his red-clover queens were first from his ted-clover queens and are the best workers 1 ever saw. The queens are very prolific. Success to the Weekly BEE JOURNAL.

THOMAS WOLFE.

Franklin, O., March 19, 1881.

The Cause of Losses in Winter. - Bees as far as I can learn, in this section of Ohio, are nearly all dead. Our most extensive bee-keeper has but 18 colonies extensive bee-keeper has but 18 colonies left out of 80; all were well protected by chaff. Another lost all—50 colonies. Others have lost all but 1 or 2. I have saved nearly \( \frac{1}{2} \), allhough some were not in as good condition to winter as they should have been; that is, they had old queens and consequently less bees that were strong and vigorous for so long and severe a winter. Why so many bees died in winter 1 do not know; yet I am satisfied that it is not all caused by the cold. If bees were in first-rate condition for winter—that is the bees themselves—and then perfectly protected, the loss would be small; but

without this condition, protection is only a partial remedy in such winters as this where bees have been confined 114 days as ours have been. Although last season was a poor one for surplus, I obtained my share and could make money. even in as poor a year as that, and if this season shall prove a good one, I want to see what I can do, as there has not been a good season since I have been in the business. The price of honey in frames is the same as last fall, but there is plenty of honey in the market at from 10 to 15 cts.; it is from hives where bees have died, and in some cases I find the honey is sour.
P. R. HUNT.

Plattsville, Ohio, March 16, 1881.

Bees Tried to their Utmost Endur-Bees fried to their timost Endurance.—My bees are doing well considering circumstances. Thave some in chaff hives and some in single-wall hives, packed with chaff, on the summer stands. Those in chaff hives are quiet and dry inside, while those in the Langtenth hives are due, and the higher wall the bass are and dry inside, while those in the Lang-stroth hives are daup, and the bees are uneasy; they cannot endure it much longer without a flight. It is now 133 days since they have been confined to their hives. There are but few bees in this country, and they are nearly all this country, and they are hearly an kept by farmers, and are put away in the fall in a kind of "live if you will, or die if you must" fashion, and most of them will be dead if this weather continues much longer. We are having another "blizzard" to-day; wind, snow and sleet, with 3 feet of old snow on the and seet, with a feet of old showing for 12 hours. This is the fourth time the rail-roads have been blockaded this winter. Does it ever get warm enough for bees to fly with snow on the ground? The of the ever get warm enough for bees to fly with snow on the ground? The snow is 4 feet deep in my bee yard. We are very much pleased with the BEE JOURNAL since it became a weekly. We could hardly get along without it.

D. S. BURBANK.

Reinbeck, Iowa, March 11, 1881.

[Bees frequently have their winter flight while the ground is covered with snow. Straw or hay should be scattered over the surface for the bees to alight on, in case they become weak or chilled. -Ep.1

My Report to Date - Is one colony dead out of 6 wintered in cellar. I put them out for a flight on March 12. 1 think they are all right. The one, I think, had too few young bees; it had been queenless for about 2 months, when I gave them a Cyprian queen late

Quebec, Canada, March 19, 1881.

## Homer Redivivus .-

| Omer Kefhyins. -| Tve read the Weekly Journal, through The advertisements, I read those, too It's just exactly what I want. For it is now the best extant; And after having such a freeze. Fill tell you something about my bees I have in cellar forty "stands," (A part of them have golden hands): Out-of doors I had forty-four. But some have died-I think a score; The brees in-doors are doing well, While those left out have gone to "The borrie from whence no traveler returns. AZARIAH WIGLIAMS.

Bees in Northern Kentucky. - Here 3 of the bees died of dysentery, and perhaps a few starved. About the middle of Nov. I fed some of my bees, and packed them, in fair condition for winter. When the cold weather commenced so suddenly I thought I would wait for so suddenly I thought I would wait for a warm day to pack the rest, but it has not yet come; the ground is frozen and it is snowing to-night. From 40 colonies in Nov. I have at the present 21 left. The 14 colonies that I fed and packed are all alive, and all but one colony are in good condition; all have brood since the middle of Jan. My 6 colonies of Italians gathered nore fall honey than all my blacks, but ceased breeding carall my blacks, but ceased breeding ear-lier in the fall and commenced later this winter. But I like them to rear queens from, if nothing else, on account of their heing readily seen when first emerged from the cell. The losses in my neighfrom the cell. The losses in my neighborhood are about as follows: A., 3 lost out of 8 colonies; B., 18 from 21; C., 14 from 16; D., 17 from 21, and many have lost all. But I have not lost all hopes yet. Success to the Weekly Bigs Journal.

Dividing Ridge, Ky., March 3, 1881.

Feeding and Extracting.—1. Will ryemeal in syrup, to feed bees in early spring answer the same purpose as when fed in candy?

2. Can an extractor be used to remove 2. Can an extractor be used to remove honey from pieces of comb as they come out of gum hives when taking up or transferring? I like the BEE JOURNAL very much, and think it is invaluable.

MRS. O. F. DEAN.

Carthage, N. Y., March 21, 1881.

[1. Yes; but we prefer giving it separately, using for that purpose unbolted rye-meal, and putting it in pans at a short distance from the hives. If pollen is needed the bees will carry it in, even though honey or syrup be exposed in close proximity.

2. Yes; all of the modern extractors will clean the pieces nicely.—Ed.]

Melange.—1. When bees are working in the surplus boxes, does it do any harm to remove a frame of sealed brood from the brood chamber once in two weeks, to strengthen nuclei, and put in a sheet of comb foundation?

2. When surplus honey is wanted in-stead of increase, is it not best to prevent swarming by giving plenty of room, and then make up the increase between basswood bloom and buckwheat, by stimu-

lating the queens?
3. How many feet to the pound should comb foundation be for brood chamber

and surplus boxes ?

When and where was the honey bee first mentioned in ancient history, and who was the first that kept them for pecuniary profit?

5. In preparing bees for winter, how many frames with two-thirds empty combs would be required for a strong colony to cluster on? I gave 6 with 2 full frames of honey; and the bees starved.

Butternut Ridge, March 21, 1881.

[The above letter was unaccompanied with the writer's name, and would have been consigned to the waste basket, had the questions not been of a general nature. Courtesy requires that the name should accompany the communication, though not necessarily for publication.

1. It does harm, in that it interferes with the reinforcement of the workers as they die from age and casualties.

2. Many successful apiarists pursue the course suggested.

3. For brood frames, 41/2 to 5 feet; for surplus boxes, if used as small starters, the same weight will answer; if full size, 10 to 12 feet.

4. Honey and bees are frequently referred to in the Old Testament. Canaan is mentioned as a land flowing with milk and honey, and when Abraham's sons went to Egypt to buy corn, they took honey with them as a present to the Egyptian ruler—Gen. 43: 11. The honey bee was extolled in verse and prose by Homer, Herodotus, Aristotle, Cato, Virgil, Pliny, Columella and other ancient writers. A more extended reference to this subject will be found on pages 5-8, of the pamphlet " Honey, as Food and Medicine," The last clause of the question we cannot answer.

5. Two are enough: three are a great abundance.—ED.]

Wintering in a Cave,—I have wintered in a cave for 4 years, with very small loss; some years none. The cave cannot be too warm, if it is perfectly dry; then there is no mildew on the combs. My bees come out stronger in the spring than when I put them away in the fall. If damp, the loss will be great and all the combs nearly spailed.

D. S. WAY.

Urbana, Iowa, March 13, 1881.

Bees Are Searce.-The bees in this section are scarce; over one-half of them have died during the past severe winter.

S. J. Davis. ter. Goldsmith, Ind., March 14, 1881.

Late Spring.—Spring was late in coming, but my bees are doing well—all breeding nicely, having already reared one litter of brood. The maple bloom is about over now. Peach buds are opening slowly. I look for a good honey season this year.

S. C. Donge. Chattanooga, Tenn., March 18, 1881.

One Haif of the Bees Dead. - About of the bees in this section, as far as ir as heard from, are dead. One man far as heard from, are dead. One man reports a loss of 149 out of 150 colonies,

but they had no care whatever. O. B. RANNEY. Kalamazoo, Mich., March 19, 1881.

Bees Carrying in Pollen.—My bees are carrying in pollen from soft maples to-day. I have lost 3 weak colonies out of 52, and 1 do not expect to lose any more. I left some on the summer stands unprotected, as an experiment, but they starved with plenty of honey in the hives; it was too cold for them to reach it.

Gilead, Ill., March 15, 1881.

Purifying Wax.—Will some of the numerous readers of the BEE JOURNAL give us the best mode of cleansing and give us the best mode of cleansing and purifying wax? I received a sample of comb foundation from Messrs. Dadant & Son which is really beautiful, it is so clear and yellow. A few hints would be of great value. I like the Weekly BEE JOURNAL. D. V. BEACOCK.

Brockville, Canada, March 22, 1881.

[Perhaps Messrs, Dadant & Son, and others, will give their methods of purifying and cleansing beeswax.—Ed.]

Wintering in Box Hives.—Bees in this vicinity, kept in box hives, have done well, and there seems to be no winter-killing or loss; but those in Langstroth killing or loss; but those in Langstroth and other movable comb hives, have suffered at a rate; of from one-tenth to one-third. I have lost 3 out of 8; those lost were in Langstroth hives; 2 Langstroths kept well; my other 3 were not movable comb. Bees here are carrying in pollen in large quantities from the silver poplar and water maple, and looking healthy and in tine condition. At first 1 did not like the change, but now 1 am delighted with the Weekly Journal. R. A. Mollyneaux. JOURNAL. R. A. MOLLYNEAUX. New Richmond, Ohio, Mar. 18, 1881.

Chaff Packing Triumphant.—I have just examined my bees after their long winter's nap, and I feel like throwing up my hat and whistling big, for I am out of the woods " for this winter. I have not lost a colony and never saw home in lotter condition at this season. have not lost a colony and never saw bees in better condition at this season. I feel very jubilant over my success, for they were not in the best condition for wintering. Our winter has been long and severe; the thermometer has stood as low as 25 below zero. My bees had no good tlight from Nov. till Feb. Chaff hives and chaff packing did the busi-ness. I winter on the summer stands. ness. I winter on the summer stands, and from observation and experience I have about come to the conclusion that, with proper protection, that is the way to winter bees. At some future time I will give a detailed account of how I packed my bees, and the material used. (for I had them packed in different ways) and my experience with the different kinds of packing. I hope that bee-keepers will report their last winter's experience and the manner of wintering minutely, and the result by so doing. I think that we will develop something that will be of lasting benefit to us all, in the way of successfully wintering bees. The Weekly Bee Journal to its a splendid thing for bee-keepers, and that it may be just as good a thing for its publisher is my earnest desire.

J. W. Henderson.
Burlington, Kan., March 15, 1881. with proper protection, that is the way

Burlington, Kan., March 15, 1881.

Portable Sheds for Winter. - I have 21 colonies of bees in portable sheds, with shingle roof (3 in each shed), packed in chaff and wheat straw. They are all right. It left 6 colonies on sunmer stands without protection and lost 3 of them; another is quite week. More stands without protection and lost 3 of them; another is quite weak. More than <sup>2</sup><sub>3</sub> of the bees in this neighborhood are dead. P. S. VANRENSSELAER. LaCarne, O., March 21, 1881.

#### CLURRING LIST.

We supply the Weekly American Bee Journal and any of the following periodicals, for 1881, at the prices quoted in the last column of figures. The first column gives the regular price of both:

### Honey and Beeswax Market.

BUYERS' QUOTATIONS.

## CHICAGO.

HONEY-The market is plentifully supplied with honey, and sales are slow at weak, easy prices. Quotable at 18@20c, for strictly choice white comb in 1 and 2 lb. boxes; at 14@10c, for fair to good in large packages, and at 10@12c, for common dark-colored and broken lots. Extracted, %210c.

BEESWAX.-Choice yellow, 20@23c; dark, 15@17.

#### NEW YORK.

NEW YORK.

HONEY.-Best white comb honey, small neat packages, 14216c.; (air do., 14216c.; dark do., 114212; large boxes sell for about 2c. under above. White extracted, 9810c.; dark, 728c.; sonthern strained, 8488c. Mesoc. BEESWAX.—Prime quality, 20@23c.

#### CINCINNATI.

HONEY.—The market for extracted clover honey good, at 8@ 10c. Comb honey is of slow sale at 16c. is good, at 8@10c. Com for the best. BEESWAX-18@22c. C. F. MUTH.

### SAN FRANCISCO.

SAN FRANCISCO.

HONEY.—The "Vigilant" takes 600 cases to Liverpool. There is a slightly improved feeling consequent upon a little more inquiry, but prices show no material appreciation. Discouraging reports are received from the southern part of the State, as to the prospects of the coming crop, but other sections give promise of an ahundant yield. With a good supply yet on the market, prices are not apt to be buoyint until the anticipated failure is more fully settled. We quote white comb. 126/15c; dark to good, 186/11c. Extracted, choice to extra white, 55/66/52c; dark nnd eandled, 56/54c.

BEESWAX—226/22/4c., as to color.

STEARNS & SMITH, 423 Front Street.
San Francisco, Cal., March 11, 1881.

## SPECIAL NOTICES.

Constitutions and By-Laws for local Associations \$2 per 100. The name of the Association printed in the blanks for 50 cents extra.

What is the meaning of 'Dec. 81' after my name on the direction-label of my paper?" This question has been asked by several, and to save nas been asked by several, and to save answering each one, let us here say: It means that you have paid for the full year, or until "Dec. 31, 1881." "June 81" means that the first half of the year is paid for, up to "July 1st." Any other month, the same.

We will send sample copies to any who will send sample copies to any who feel disposed to make up clubs for 1881. There are persons keeping bees in every neighborhood who would be benefitted by reading the JOURNAL, and by using a little of the personal influence possessed by almost every one, a club can be gotten up in every neighborhood in America. borhood in America. Farmers have bornood in America. Farmers have had large crops, high prices, and a good demand for all the products of the farm, therefore can well afford to add the BEE JOURNAL to their list of

When changing a postoffice address, mention the *old* address as well as the new one.

www We have prepared Ribbon Badges for bee-keepers, on which are printed a large bee in gold. Price 10 cents each. or \$8.00 per hundred.

.-. The Volume of the BEE Jour-NAL for 1880, bound in stiff paper covers, will be sent by mail, for \$1.50.

Notices and advertisements intended for the Weekly BEE JOURNAL must reach this office by Friday of the

\*\*Instead of sending silver money in letters, procure 1, 2 or 3 cent stamps. We can use them, and it is safer to send such than silver.

Ladies who Appreciate Elegance and purity are using Parker's Hair Balsam. It is the best article sold for restoring gray hair to its original color and beauty.

The date following the name on the date following the name on the wrapper label of this paper indicates the time to which you have paid. In making remittances, always send by postal order, registered letter, or by draft on Chicago or New York. Drafts on other cities, and local checks, are not taken by the banks in this city except at a discount of 25c., to pay expense of collecting them. collecting them.

Premiums.—For a club of 2, weekly we will give a copy of "Bee-Culture;" for a club of 5, weekly, we will give a copy of "Cook's Manual," bound in cloth; for a club of 6, we give a copy of the Journal for a year free. Do not forget that it will pay to devote a few hours to the Bee Journal.

Sample copies of the Weekly BEE JOURNAL will be sent free to any names that may be sent in. Any one intending to get up a club can have sample copies sent to the persons they desire to interview, by sending the names to this office.

Any one desiring to get a copy of the Constitution and By-Laws of the National Society, can do so by sending a stamp to this office to pay postage. they desire to become members, a fee of \$1.00 should accompany it, and the name will be duly recorded. This notice is given at the request of the Executive Committee.

It would save us much trouble, if all would be particular to give their P.O. address and name, when writing to this office. We have several letters (some inclosing money) that have no name. Many others having no Post-office, County or State. Also, if you live near one postodice and get your mail at another be sure to give the abmail at another, be sure to give the address we have on our list.

At the Chicago meeting of the National Society we were requested to get photographs of the leading apiarists, to sell to those who wanted them. We can now supply the following at 25 cents each: Dzierzon, the Baron of Berlepsch, and Langstroth. The likeness of Mr.Langstroth we have copied, is one furnished by his daughter, who ever "it is the only one ever taken when he was in good health and spirits." We are glad to be able to secure one of such a satisfactory nature.

We have filled orders for quite a number of Binders for the Weekly BEE JOURNAL. We put the price low, 30 per cent. less than any one else could afford to sell them, for we get them by the quantity at wholesale and sell them the Bee Journal to their list of papers for 1881.

Hundred of Men, Women and Childer of Parker's Ginger Tonic are the least vidences in the world of its sterling worth. You can find these in every community.—Post. See advertisement. 9w4t their Meakly at wholesale and sell them the quantity at wholesale and sell them at just enough to cover the cost and postage, the latter being 21 to 23 cents, on each. We do this to induce as many as possible to get them, and preserve their Weekly numbers. They are exceedingly convenient; the Journal being always bound and handy for reference. The directions for binding are sent with each one.

## Wire Nails.

have concluded to carry a stock of them, and can fill orders for any quantity promptly. For mailing Sections, Cases, Frames, Racks, Crates, &c., they have

The entire length of the nail being the same thickness, they never loosen as ordinary from mails will, and are not as liable to bend or break.

From the assortment of lengths given in the table below, any kind of nailing may be done with these nails, even to making large boxes.

## Books for Bee-Keepers.

Cook's Manual of the Aphrey. Entirely rewritten, greatly enlarged and elegantly illustrated, and is fully up with the times on every conceivable subject that interests the adardst. It is not only instructive, but intensely interesting and thoroughly practical. The book is a masterly praduction, and one that no bee-keeper, however limited his menus, can afford to do without. Cloth, \$1.25; paper covers, \$1.00, postpaid. Per dozen, by express, cloth, \$12; paper, \$2.0.

Quinby's New Hee-Keeping by L.C. Root— he author has treated the subject of hee keeping a manner that cannot fall to interest all. Its style is plain and foreible, making all its readers sensible if the fact that the author is really the master of the object. Price, \$1.50.

Novtee's A H C of Ree-Uniture, by A. I. Root. This embraces "everything pertaining to the care of the honey-bee," and is valuable to beginners and those more advanced. Cloth, \$1.25; paper, \$1.00.

King's Bee-Keepers' Text-Book, by A. J King.—This edition is revised and brought down to the present time. Cloth, \$1.00; paper, 75c.

Langstroth on the Hive and Money Bee This is a standard scientific work. Price, \$2.00.

Blessed Bees, by John Allen.—A romance of bee-keeping, full of practical information and contagious enthusiasm. Cloth, \$1.00.

Hee-Culture; to Successful Management of the Apiary, by Thomas G. Newman,—This pamphlet embraces the following subjects of the Apiary—Honey Plants—the Rearing—Feeding—Swarming—Dividing—Transfern—Flainizing—Introducing Queens—Extracting—Queens—Introducing Queens—Extracting—Queens ing Honey for Market, etc. It is published in Fig. 18th and German. Price for either edition, 40 cents, postpaid, or \$3.00 per dozen.

Food Adulteration: What we cut and should not eat. This book should be in every family, where it ought to create a sentiment against the adulteration of food products, and demand a law to protect consumers against the many health-destroying adulterations offered as food. 200 pages. Paper, 50c.

The Dzierzon Theory; presents the fundamental principles of bee-culture, and furnishes a condensed statement of the facts and arguments by which they are demonstrated. Price, 15 cents.

which they are demonstrated. Price, 15 cents.

14 oney, as Food and Medicine, by Thomas G. Newman.—This is a pumpilet of 21 pages, discoursing upon the Ancient Histories flees and Honey; the nature, quality sources, and florey as on order of the Market; Honey as an advantation of Honey food, they have the control of the food of the Market; Honey as an expensive fooding, Fooding, William of the Market; Honey as an expensive fooding, Fooding, William of the Market; Honey as an expensive fooding, and Honey as Medicine, follows, by many useful Recipes. It is intended for consumers, and should be scattered by thousands all over the country, and thus assist in creating a demand for honey. Published in English and German. Price for either edition, 6c; per dozen, 50c.

Wintering Hees.—This pamphlet contains all the Prize Essays on this important subject, that were read before the Centennial Bee-Keepers' Association. The Prize-425 in gold—was awarded to Prof. Cook's Essay, which is given in full. Price, 10c.

The 11 ive I Une—Being a description of the hive nsed by G. M. Doolittle. Price, 5c.

Extracted Honey; Harvesting, Handling and Marketing.—A 24-page pamphlet, by Ch. & C. P. Dadant, Hamilton, Ill. This gives in detail the methods and management adopted in their apiary. It contains many good and useful hints, and is well worth the price—15c.

Practical Hints to Bee-Keepers, by Chas. F. Muth. Cincunnati, Ohio; 32 pages. This pamphlet gives Mr. Muth's views on the management of bees, and embraces several of his essays given at Conventions, etc. It will be read with interest by beginners as well as those more advanced in the science of heeculture. Price, 10c.

Kendall's Horse Book—No book can be more useful to horse owners. It has 35 engravings, illustrating positions of sick hoses, and treats all diseases in a plant and comprehensive manner. It has a large number of good recipes, a table of doses, and much other valuable horse information. Paper, 25c.

other variable noise information. Paper, 25c.
Chicken Cholera, by A. J. Hill.—A treatise on its cause, symptoms and enre. Price, 25c.
Moore's Universal Assistant contains information on every conceivable subject as well as receipts for almost everything that could be desired. We doubt if any one could be induced to do without it, after having spent a few hours in looking it through. It contains 480 pages, and 300 engravings. Cloth, \$2.50.

Ropp's Easy Calculator.—These are handy tables for all kinds of merchandise and interest. It is really a lightning calculator, nicely bound, with slate and pocket for papers. In cloth, \$1.00; Morocco, \$1.50. Chenje edition, without slate, 50c.

Sent by mail on receipt of price, by

THOMAS 6, NEWMAN, 974 West Madison Street, Chicago, III.

Free of postage in the United States or Canada. Postage to Europe 50 cents extra.

Entered at Chicago post office as second class matter.

## Interesting Letter from Singapore.

The following letter from Mr. Benton, from Singapore, will be read with inter-That city is a great seaport near the Islands of Borneo and Java. Mr. Benton's search after those large bees -Apis dorsata—is a herculean task, and his trip thither will be well worth a place in history. Here is the letter:

FRIEND JONES: When in Ceylon I plunged into the jungles, first in this di-rection and then in that, and followed out every clue that I could obtain: although on every side 1 was told there existed "a large bee," which the natives call bambera, it was not until just before came away that I ascertained any thing reliable regarding the habits and whereabouts of this wonderful insect, which I feel safe in saying is the long talked of Apis dorsata itself; though it was too late for me to get to the places where I could see this bee and Still reach this steamer. As I return to Ceylon, and am likely to see Apis dorsata elsewhere also, I comforted mysata elsewhere also. I comforted myself regarding the disappointment experienced at not seeing this bambera before my re-embarkation.

I will speak in the order of their size, of the bees found in Ceylon, giving the Cingalese names used there.

Kana Mee Meso belongs to the Trigohoney bee, although it gathers pollen and some honey, and lives in swarms with a queen. In a jungle a few miles from Kaltura, on the southwest coast of Ceyaueen. lon, I found a small bee which contained a nest of these minute, stingless bees. A tube about <sup>3</sup>/<sub>4</sub> of an inch in diameter and a foot long, composed of propolis and particles of wood, hung from the hole of the tree, and through this tube all the bees entered. It seems ameter and a foot long, composed of propolis and particles of wood, hung plan of taking with me for introduction to Cyprus a lot of cocoanut palm trees, this tube all the bees entered. It seems this is a means of keeping out larger insects. The tree was cut and the nest in Ceylon. As the date-palm, the or-

The cells are built in irregular bunches like those made by common bumble bees. Those cells containing brood were about the size of a grain of rice, while the honey and pollen cells were as large as the smaller cells made by bumble bees. The workers are somewhat less than 3-16 of an inch long, (about 5-32) have large heads, and very small abdomens, the latter seeming blunt, and abbreviated, so to speak. These bees fly swiftly, and look odd enough as they come in loaded with minute pellets of pollen, which is packed on their hind legs as with other bees. They are black.

The queen is large, her abdomen being so great as to dwarf in appearance all other parts of her body, and so disand other parts of her body, and so unsable her as far as flying and rapid movements are concerned. Of course there can be no practical value in these bees, but I tucked the nest in a box about 6 inches square and 2 deep, or rather a part of the brood and honey, and brought the syrang about. They have been fix the swarm along. They have been fixing up their new home quite bravely.

Daudual-Meso is a small bee which I ive not seen, but which I do not believe is likely to prove valuable, since it is so small. Its comb is composed of regular hexagonal wax cells, like all comb of Apis, but there are \$1 cells to the square inch. I have in my possesthe square inch. I have in my possession a small piece.

Mee Meso are the Cingalese words

Mee Meso are the Cingalese words signifying "honey bee,," and this is the bee from which, aside from bambera, most of the honey and wax come.

Bumbera, all accounts agree, exists plentifully in the jungles of Ceylon, but I found just before I came away, only rarely near the seashore, I failed to find it within 10 miles of the coast. I was glad to get accounts from persons who have seen these bees and their trees, and have measured the lengths of their combs; observing gentlemen, too, whose word can be relied upon. They whose word can be relied upon. They say these bees, which I feel sure are of the species Apis dorsata, attach their combs to the branches of trees, usually some lofty trees of the primitive forest, and a gentleman who has often seen them, says they build combs 8 feet long. them, says they build combs 8 feet long. Another once measured a comb which he found to be 6 feet long. The first mentioned gentleman says he has seen 30 natives with earthen pots each receive a load from one bambera bee tree, and has seen a swarm of these bees nearly a half mile long. When I visited the Government Museum in order to obtain information as to whether they to obtain information as to whether they knew anything of these bees and where they were to be found, the natives having only succeeded in finding deborah, (a large hornet) with its nest, for me. I was at once taken by one of the directors to this gentleman, as the one from whom the most information could be obtained.

The Cyprian and Palestine bees I have with me are doing finely. Those left in Ceylon will serve to introduce the speceyon was serve to introduce the spe-cies A. melifica, and will establish in that wonderful, productive Island an in-dustry that I feel sure will thrive there and be a source of revenue to the inhabitants and the government.

ange, the lemon, the fig, the banana and the pomegranate are already growing in 'yprus, I believe these new fruits will hrive and find favor. Financially, of thrive and find favor. course, it is an experiment, yet I believe it promises well; at any rate it will not cost much to try it.

Except this paw-paw, I failed to find any fruit or grain that is likely to thrive of North America. Cinnamon, coffee, tea, betel nuts, precious stones and cocoanuts and oil are, with einchona bark, the principal exports of Ceylon. I talked with various exporters, but all had their agents in N. Y. and Canada, and desired no change. None of them would sell, of course, direct to the firm, when possessing an agent in America. Upon my return I will see what further can be ascertained as to "out-of-the-way products." It is hard to get

of the way products." It is hard to get any prices, and would in most instances be difficult to obtain a quantity worth while to ship.

From Arabia, coffee, gums, perfumes and pearls come. At Aden I was told that the best Mocha coffee could be got that the best Mocha confectould be got for one shilling (or 24 cts.) per lb. In large quantities I think it can be got still cheaper. I should think precious stones (sapphire, jasper, &c..) gums, cof-fee, cocoanut oil, cinnamon oil and pearl would now best perhaps also ivery and would pay best, perhaps also ivory and ostrich feathers. At Aden I found some large wheat, but kinds were mixed, or else the variety is not a fixed sort. This portion of the world produces little or no grain besides rice.

I have obtained seeds of a number of flowering plants and trees, some of which I know yield honey, and others that look as though they might were there bees to gather it. We expect to reach Singapore to morrow forencon. will take the first steamer for Batavia, which will likely leave in a day or so.

FRANK BENTON.

For the American Bee Journal.

# Cause of Bee Cholera or Dysentery.

G. M. DOOLITTLE.

I have noticed in several articles a statement quite similar to this, which is taken from Mr. James Heddon's article in the February number of the Bee-Keepers' Instructor: "Every bee-keeper experience who lives in our northern latitudes has witnessed enough to know hatitudes has witnessed enough to know that cold or confinement, or both, do not cause bee cholera or dysentery."

Now, I claim the title "bee-keeper" (whether of experience or not I dare not say), and live in the "northern latitudes," yet I cannot be one of the number above styled as "every," for I believe confinement doescause the so-called dysentery, and hope to so clearly show it in this article that, you will so acknowless. this article that you will so acknowledge also.

First. I once produced dysentery (I do not believe this is a disease, but merely an accumulation of the feces) in its worst form, the latter part of June, by confining a lot of bees to the hive for 10 days. A frame of brood was taken from the hive with the adhering bees. and also a frame of honey with the bees which were on that, and placed in an empty hive to form a nucleus, the bees being confined to the hive for three or

ing there came on a cold storm and bad mg fifther came on a cont storm and bad weather custied, so the bees could not fly for six more days. On the tenth day the sun came out, and the bees from these nuclei (7 in number) were so loaded that they could scarcely fly. An examination revealed that they had eaten on an average about 2 lbs, of honey in each nucleus. Nucleic world but a few days nucleus. Nuclei made but a few days before, which had flown 2 or 3 times before the bad weather, were not eager to fly, and showed no signs of dysentery, neither did our full colonies; nor had they eaten an undue amount of honey. The trouble here was evidently confinement, which caused the bees to worry and thereby consume an undue quantity of food, thus producing a necessity to void the excrement, or dysentery, if you please to call it so.

Again, in the fall of 1878 our bees were prepared for winter in the best possible shape, and had nothing but white honey in their hives, said honey being collected the early part of July, for we had no fall honey. Sixty colonies were put in the cellar, and 90 left on the were put in the cellar, and 90 left on the summer stands, two-thirds of which were packed with chaff and straw. Winter set in early, and the weather was so cold that no bees could fly with safety for nearly 4½ months. At the end of 4 months some of our best colonies were dead, with the combs and hives soiled badly, while others sitting right alongside of them were in as fine condition as could be and remained right alongside of them were in as time condition as could be, and remained thus, coming out strong in the spring. If it was "bacteria" in the honey, why did not all die, as all had the same stores? We also placed 60 colonies from the same yard in the cellur on the 1st of Yayambar, and the cellur on the 1st of November, and did not set them out till May 1st, and 55 of the 60 came out in good condition, while we only saved 15 out of the 90 out-doors—75 dying with the dysentery, so-called. If it was infection of the honey, why did not those in the cellar die also, and especially as they steed 6 ments by confinement 2. They they stood 6 month's confinement? past winter has shown the same results, only our loss is but about 10 per cent.

so far.

Now I will give my conclusion. From

practical experience I have been forced to the conclusion that confinement is the cause of all wintering troubles, surely, bees do not die from what they eat in July weather when they can fly. But confine them to the hive with July weather, and they cannot live one-third as long as in cool or cold weather. That That confinement is the result whenever the mercury falls below 40° to 45° in the shade, and as surely as the mercury stays below this for 60 days in succession, bees not properly protected will suffer therefrom, and if properly protected, 120 days will more or less burt those on the summer stands; that 180 days' continement in a good cellar can be endured by the bees as well as 120 days in wellprotected hives, or 60 days with no protection on the summer stands; that if 60 days more of confinement is added in either case, not 1 colony in 10 can sureither case, not recordy in 10 can survive, no matter what the food is nor the surrounding conditions. Now, we come to our last point, which is, that instead of the trouble being in the kind of honey eaten thus producing dysentery, the trouble is in the quantity eaten, and as the quantity consumed is to the number of days the bees are confined, so is their four days, when the entrance was opened in the evening. Early the next morn-for instance, a fair-sized colony may

does not.

consume  $1^{1}_{2}$  lbs. of honey per month, and endure confinement without soiling the combs for 6 months; now, if the consume 6 times this amount in consume 6 times this amount in 2 months, they must fly at the end of that time or the combs will be soiled very soon thereafter. We often read, "My bees wintered well and consumed but very little honey," while the fact was that their consuming but little honey was the reason they wintered well. Thus we are able to answer the question why one colony dies and another at the why one colony dies and another at the side of it does not. It is because one gets discontented and consumes large quantities of honey, while the other

Now comes the rub: why does one colony get discontented within I month after being confined, and another does after being confined, and another does not under 3 or 4, or in case of cellar wintering, 6 months. Well, I will be candid and say I do not know; but I do not believe the cause is in the honey altogether. One thing Mr. Heddon and myself will agree on I am sure, and that is, if as soon and as often as a colony gets uneasy and goes to eating honey ravenously they could have a day to fly, all would be well, even if such a colony was obliged to fly 3 or 4 times where another did not have to but once.

was obliged to By 3 or 4 times whereanother did not have to but once.

To keep bees quiet the longest possible time I would recommend: 1st. A good bee cellar in a bank, covered all over with no less than 3 feet of earth, and an even temperature maintained inside at 44 to 45: 2d. Hives so coninside at 44 to 45; 2d. Hives so constructed that chaff could entirely surround the bees to the depth of 4 inches. To sum up, we should winter one-half our apiary one way and one-half the other, inasmuch as our winters vary so that one winter has come out the best on summer stands, and another the best from the cellar. I will refer to this subject again in the next Weekly BEE

Journal.
Borodino, N. Y., March 22, 1881.

For the American Bee Journal.

## Extracting Bees.-The New Industry.

H. T. COLLINS.

As the exigencies of the times have created the new industry of "extracting dead bees" from the cells, and as many of the bee-keeping fraternity may want to do so without delay in order to some time. Large my plan as I think save time, I give my plan, as I think the one suggested by our editor, though good in the main, is apt to break the combs too much. The necessary tools are a small pair of tweezers (such as taxidermists use), a light and sharp darning needle, and last but not least, a shallow tin pan, say one inch deep and 13%4x17%4 inches. Every keeper of 10 or more colonies should have one or more pans—they just fill the bottom of a 10frame Langstroth hive, and are as handy as a pocket in a shirt. Instead namy as a pocket in a shirt. Instead of the pan, a common table waiter will answer. Sitting in a good light, place the pan lengthwise across the lap, and lay the frame across the pan, but parallal with the law. lay the frame across the pan, but paral-lel with the lap. The use of the pan is to give a convenient rest to the frame, and to hold the dead bees. If you are right-handed, let the top of the frame be towards the right hand, if not, rice versu. Holding the tweezers in the hand, which is right (often the left one), grasp the bee and pull it out slowly and gently, and with the motion of the hand towards the top of the frame. As in the natural position, the base of the cell is horizontally the lowest, the above mentioned motion extracts the bee with the least friction. But in some combs they will stick so tight as to break off at the junction of the abdomen, and to at the junction of the abdomen, and to prevent this, with the durning needle pierce the thorax as it comes to the edge of the cell, and by its help you can nearly every time drag out the tootightly lodged bee. A cap of warm water will be convenient in removing the sticky deposit that will often adhere to the end of the tweezers. To the inexperienced, the above may seem to be a slow and tedious way of extracting a slow and tedious way of extracting bees, but a little practice will make one please communicate it promptly, as this new industry promises, from the weekly reports, to be a large and growing one. Jacksonville, 111.

For the American Bee Journal. Separators for Surplus Honey.

JAMES HEDDON.

For the benefit of some who do not as yet understand all my argument against the use of separators 1 wish to add, that I am well aware that the system of sections within frames hung in a super, is entirely impracticable without the use of separators. I know too that, as Messrs. Greiner Bros. remark, bees take more kindly to wood than to tin or glass, and there is just where the trouble comes, as they sometimes kindly attach the sides of the combs to them. Some seasons, under peculiar circumstances, the loss of honey by the use of separators might, as Greiner Bros. say be very slight, but in many seasons they will be found to be a serious detriment to the amount of surplus obtained. But why not use a system that does not need them, and is much handier than the super system besides?

I supposed that the younger bee-keep-

ers, who keep posted, knew that many old producers on a more extensive scale one producers on a more extensive scale never used separators at all, and of that class who did many others are laying them aside. Bees do finish up their combs full better with separators, because as the season draws to a close they are less inclined to start another comb in case of them. in one of those little compartments, and as long as there is honey coming in they finish with it to keep from *perfect* idleness. I think the unfinished combs are just so much extra. If it is "strange" that I should declare against the use of that I should declare against the use of all separators, while still many prominent bee-keepers use them, how dare you, Messrs. G., declare against tin, compared with wood, when you know that tin is the popular material? Galileo said, "The world is round;" all others said, "It is flat," and there being more of the "flats" than Galileos, these "thist" put their greatest scientist be-

more of the "flats" than Galileos, these "flats" put their greatest scientist behind the prison bars.

Before I close, I wish to call the attention of the readers of this paper to the able article of A. B. Weed, on "Queen and Supply Trade," in the Bee Journal of March 23d. I think all beekeepers, whether supply-dealers or producers strictly, if posted upon the mints thorain taken will say "Thanks". ducers strictly, if posted upon the points therein taken, will say, "Thanks

to Mr. Weed. Dowagiac, Mich., March 26, 1881.

For the American Bee Journal.

## Pure Liquid Honey in Glass Jars.

CHAS. F. MUTH.

The above subject is one which has provoked considerable comment, and it appears we are not quite done with it yet. I dare say that there is not a dealer of any note in Cincinnati, by this time, of any note in Cincinnati, by this time, who imagines that my jar honey is anything but pure honey, or who suspects any honey when it comes from my store; and I am just as positive in the statement that there is not a dealer in Cincinnati, having extracted honey from New York or Chicago in store, who does not believe it to be glucosed. There is hearly anytherly in our community who hardly anybody in our community who suspects the purity of the honey when my label is on the jar. Jar-honey, in general, is not mistrusted any more in our city, unless the jar contains besides the liquid, also a piece of comb honey. Such is the case in Cincinnati, to all ap-pearances, and 1 am willing to be corrected if wrong.

The subjoined letter from a party in

New York, and my answer to them, show an interesting difference in the state of the market for extracted honey state of the market for extracted honey in our city and New York, the home of Mr. W. M. Hoge, Wm. Hogue or John Long. To avoid misunderstanding, I may state that Hoge, Hogne or Long, while in New York, was bottling honey for the firm of Thurber & Co. In explanation of the letters following, I may state that the editor of the Cheining. state that the editor of the Cincinnati Grocer had been recommending my honey to Messrs. Guernsey & Co., N. Y., who opened correspondence with me, and to me he had recommended them as perhaps the best party to introduce my honey in the New York market. The result was that I sent them I gross of 1 lb. jars and I gross of ½ lb. tumblers,

at cost, on 60 days' time. The honey commenced granulating in the course of a month or more. This fact, and the general mistrust to extracted honey in New York must be taken into consideration to do the following correspondence justice:

New York, March 17, 1881. Mr. C. F. MUTH—Dear Sir: Enclosed please find bill of lading for the honey Enclosed sent us. We find it totally impossible to sell the goods, as parties here are afraid of glucose, etc. We waited for parties to decide about them, and they concluded not to take them. We are sorry, but such is the case. We have retained one box of each, bottles and tumblers, to pay us for the freight paid on goods here. Yours very respectfully, GUERNSEY & CO.

To which I replied as follows:

Messrs. Guernsey & Co.—Gents: Your favor is at hand. I expect the return of my honey with all the charges deducted you feel disposed to make. I had supposed that there were some men in your city with enough sense to determine the difference between honey and glucose. My honey is strictly pure, and geneose. My noney is strictly place, and I will pay you \$100 if you will prove that I am wrong. Yours truly, Chas. F. Muth. Cincinnati, Ohio, March 21, 1881.

[We were shown quite recently a letter received by a prominent dealer in strictly pure honey in this city, from a correspondent in Virginia, who had ordered and received from him a keg of honey. They say: "The keg of honey came to hand on the 25th; you may imagine my chagrin on opening the package and finding the contents solid. In its present condition it is of no value to me." Although a dealer, we suppose this was really the first package of strictly pure extracted honey he had ever seen, or he would have felt pleasure, instead of chagrin, to find it granulated solid. The truth is, the public have been so much deceived with a sourious article in liquid form, that many do not know the genuine when they see it. A bee-keeper or person perfectly familiar with honey in a northern or central latitude, would require something more convincing than the mere assertion of a respectable grocer that his honey was strictly pure, if not candied or granulated in cool weather.—ED.]

> For the American Bee Journal. How to Separate Swarms.

> > BRAY & SEACORD.

An experience of 20 years with bees has taught me to wait upon them and not to have them wait upon me; in not to have them wait upon me; in other words, always have your work ahead of time. Next, to have your bees in strong condition at the time of the first flow of honey. The great mistake of beginners is to aim at too large an increase, either by division or natural swarming. If the season is good, an increase of 3 from each colony is a plenty; if a medium season an increase of one from each colony is enough.

The brood chamber is the mainspring to work upon for a good yield of honey.

The brood chamber is the mainspring to work upon for a good yield of honey. We allow no queen to live over 3 years, and if not a prolific queen she only lives one year. We allow no brood comb to remain over 3 years in the centre of the hive; by this plan we get fine developed bees, and of longer life.

Our plan of separating swarms of 2

next morning; then push the box cover lengthwise of the box and you will observe each queen with her colony clustered by themselves; now place the division board between each cluster,

the division board between each chister, push the cover back again over the cluster and hive at pleasure.

The present season is fully 6 weeks ahead of last season; drones were in the air on the 28th of Feb. We keep our colonies in a condition so that the queen can breed up to her full canacity. The can breed up to her full capacity. The Italian queens we received from the BEE JOURNAL apiary last fall. wintered well, and we now have several nuclei started for queen-rearing, as we mean to Italianize all of our bees by the end of the present season. The prospects were never better than now for a booming good year.
At some future time we will give our

At some future time we will give our experience in wintering bees in a cold climate on 4 lbs. 2 ounces of honey percolony, before chaff packing was invented.

If a Syrian queen cross with the black drone, would not this cross produce the Italian bee? Success to the BEE JOUR-

NAL. Warthan, Cal. March 15, 1881.

Iff the Italian bee is a hybrid, and originally produced by mating the black drone with the Syrian queen, then, of course, a like cause will again produce a like effect; but if the Italian bee is a distinct race, then no crossing of other races will produce it as a fixed type.-ED.1

For the American Bee Journal.

## Raspberry as a Honey Plant.

D. D. PALMER.

The raspberry can be grown in any land that will produce a crop of corn or potatoes. It furnishes a fine quality of honey, and a delicious fruit, coming immediately after strawberries. Sandy or light soils produce a better flavored fruit but not so much nor as large as

fruit but not so much nor as large as clay soils.

The ground should be spaded or ploughed deep, and raked or harrowed thoroughly so as to pulverize it. If you get plants by mail, dip them in water as soon as received and bury the roots in moist shady ground until you are ready to set them out. Plants can be sent by pail with as much certainty of sent by mail with as much certainty of arriving in good condition as if carried personally or sent by express. Handle so as to expose the roots to the sun and wind as little as possible. For garden or field culture plant 2½ or 3 feet apart in the row and the rows 6 feet apart. A convenient implement to use apart. A convenient implement to use in setting any small plants is called a dibble, made similar to a mason's trowel, and cost me 25 cts. each. Make the holes deep enough to take in the long roots without doubling them up. Spread the roots out like a fan, fill with mellow soil and pack snugly among the roots, if the ground is dry pour in the roots, if the ground is dry pour in water before filling up, then fill up with dry or moist soil, leaving the surface loose and mellow. If dry weather prevails, remove the top soil and pour in plenty of water; after the water has settled replace the soil. They may be cultivated the same as corn, being careful not to cultivate too deep as some of the roots grow near the surface.

careful not to cultivate too deep as some of the roots grow near the surface. Cabbage or other root plants may be planted and cultivated among them the lirst season. Fruit trees may be planted with them in the row.

There are several ways of training the bushes; some use stakes. This we consider an expensive practice, unless it be for garden planting, when very close planting is required and it is not wished to have a spreading bush. Our method consists in training them while developed bees, and of longer life.

Our plan of separating swarms of 2 or more, when they come out and cluster together, may be of benefit to some. It is as follows: Make a box 3 feet long (or any size that will fit the frames of your hive), make one entrance to the box for the bees to pass in and out; make a tight cover to fit the box, with cleats on 2 sides, no end cleats; make 3 or 4 division boards; then the box is ready for hiving the bees.

Now take the box and hive the cluster of 2 or more swarms, and as soon as all the bees are in the box, put it in a shady place, and let it remain there until the grow; the second season cut out the dead wood and train the laterals so as to make the rows like a hedge; nip or cut off the new shoots when 3 feet high. In this way they bear larger and better fruit, are more convenient to pick, and are not blown down by the wind, as the

are not blown down by the wind, as the bushes support each other.

The red varieties are increased by suckers or spronts from the roots. They may be cultivated 2 seasons, and if needed for honey more than choice fruit, they may be allowed to occupy the ground. The black caps are increased from tips, i.e. by the ends of the vines taking root. The Doolittle, Mammoth Cluster and Home Sweet Home are especially adapted to cultivate in hedge rows, on account of their stock canes. stock canes

Farmers might load their tables with this delicious, health giving fruit the year round, by setting 25 plants of Doo-little for early, and 100 of Sweet Home for late use and canning.

New Boston, Ill.

For the American Bee Journal.

# Apis Americana.

E. A. THOMAS.

There has been much discussion of late about "How to obtain the best race of bees," and I notice there is a great diversity of opinion in regard to it. I the fully agree with the editor of the American Bee Journal that the coming bee will be the Apis Americana, a cross between our present Italians and some other race, and I believe that, although there are but few who hold that opinion now, the time is not far distant when the majority of the apiarists of Amer-ica will acknowledge the superiority of the American strain of Italians.

the American strain of Italians.

During the past few years there has been a mania among bee-keepers for imported stock which has steadily increased up to the present time, but which I sincerely hope has now reached its height. Do not understand by this that I object to all importations for I do not, but only to those careless and almost reckless ones that instead of improvential. reckless ones that, instead of improving, will cause the deterioration of our ing, will cause the deterioration of our present excellent strain. So long as queen breeders in Italy know that any queens they may see fit to send to America will be accepted just because they came from Italy, just so long will some of them take advantage of such knowledge to ship to this country queens they would not be willing to use themselves and which American because themselves and which American because selves, and which American bee-keepers would not accept as a gift if they knew what stock they sprang from. But only let them understand that they must send only the very best and purest that Italy can afford, or lose the American Italy can afford, or lose the American trade, and they will be more careful how they try to impose upon the credulity of American bee-keepers. There are many good reliable breeders in Italy, and those who are desirous of importing should search them out and give such their orders, and give all others a severe "letting alone." But to return to my subject. When an apparist becomes, satisfied that he has an excellent strain of bees he should be very careful how he introduces new blood into his apiary, I care not from what source it comes whether from Italy or a home breeder, until he has thoroughly tested it and found it to be good. Many a beekeeper after having obtained a class of bees that did credit to America and which bid fair to become worthy of the name Apis Americana, not content to name Apis Americana, not content to let "well enough alone," has ruined his stock by introducing foreign blood that was as worthless as it was cheap. For the improvement of our present strain of bees. I would suggest that queen breeders exchange queens from their working stock and make a careful record of the result of the cross. When they get a greet last is universal to the control of the cross. get a cross that is an improvement on their own bees let them breed from it and introduce the blood into their apiary. Thus by crossing the best blood in the country we may hope to obtain a strain of Italians that will rival those found in Italians that will rival those found in Italy, and which will be exported to all parts of Europe.

As regards the color of our bees, I beg to differ with those who consider it necessary to breed dark colored bees in order to obtain good honey gatherers. I have bred both dark and light colored,

and I am satisfied that my present strain, which is as handsome as any one need wish for, has excelled anything I ever had or saw. If breeders will work ever had or saw. If breeders will work carefully and use every means in their power to improve their bees, we may live to see Mr. Newman's prophecy come true, and the Apis Americana have a world-wide fame.

Coleraine, Mass.

Translated from Blenen-Zeltung by Greiner Bros.

## Fertilization a Crippled Queen.

DR. DZIERZON.

In looking over a nucleus the past season, I found a young Italian queen just hatched. She was very large and beau-tiful, but in trying to make her flight she fell to the ground, because of her left wing being considerably shorter, and she could not rise, although she made every effort. If I had possessed a surplus queen, or even a queen-cell, I should have disposed of her; but as I had not, I left her in the hive, hoping that she might gain strength enough to enable her to make her wedding trip.

Two days after Hooked again and found my queen there still, and my experiments with her proved that she was as unable to fly as before. It occurred to me to shorten her long wing to produce me to shorten her long wing to produce equilibrium. She could then fly some, but dropped to the ground again. After I had trimmed her long wing down to the size of the crippled one, she succeeded in keeping herself up in the air for quite a while, although it seemed very hard work for her, and she finally reached her hive. I let her run in, then fixed an alighting-board, that she might have a chance to run from the ground no to her hive, if compelled. np to her hive, if compelled.

On one of the following days I was in

the apiary again at noon, and on look-ing about I noticed great excitement in one of the neighboring hives near said nucleus. When I opened the hive I found the short-winged queen in there balled, but not yet injured. Undoubtedly she came out to meet a drone, and on returning entered the wrong hive, which, when we consider her clamsiness. could not be wondered at. I picked her out of the ball, and took her back to he own hive. A few days after I found her depositing eggs, and she proved to be fertile; but whether she was fertilized on that trip, or whether she made another, is not certain.

## Read before the N. E. Convention. Best Method of Marketing Honey.

GEO, W. HOUSE.

In writing upon this subject I fully realize the difficulties of the task before me, and also the differences of opinion that exist on this interesting subject, and one that is of such vast importance to the honey producer of to-day. We are yet in the infancy of this enterprise, and time will doubtless reveal many changes and improvements where now we think we have attained perfection. Of course practical bee-keepers will em ploy all their energies to keep up with the times, and give their patrons the benefit of new developments as soon as they are proved to be improvements. We should ascertain what the market demands and then dilligently apply our selves to the work, in order to reap the reward.
We talk of supply and demand; of

We talk of supply and demand; of overstocking the markets and overstocking the land. But in solving the problem of "marketing," man's inventive genius is called upon to provide the necessary elements, whereby the desired results may be attained without increased expense to the consumer or decreased profit to the producer. This is a practical age and requires practical inventions, to be used in the race for

inventions, to be used in the race for the "mighty dollar."

There need be no fear of overstocking the markets. Honey is being used by many manufacturers in the liquid form, and its depend is increasing through. and its demand is increasing through-out the land. Honey in the comb is finding its way to the tables of thous-ands of families throughout all Europe, where till recently it was never seen. Thus the question of overstocking the market is nearly settled. All bonor to energies in this grand undertaking. There are but few of us that realize the benetits of the exertions put forth by this great firm in finding a market for our products. Their undertaking has been crowned with success, and to them we owe our sincere thanks if nothing more. The markets of the world are open to our products, and it is now our duty to see that those markets are not ruined through any fault or neglect on the part of the American producer. We must also have united action looking toward the prevention of adulterations.

toward the prevention of adulterations. We must have co-operation in marketing honey, to produce the most satisfactory results. We have seen what wonderful results have been accomplished by associate action, and by a combination of interests. The great enterprises of to-day, that are so astonishing in their magnitude, are the results of associated effort and this is sults of associated effort, and this is destined to revolutionize the business operations of the world. We have seen what wonderful results have been accomplished by the associated system of dairymen. What unity and action has dairymen. What annly and action has done for dairying and other branches of industry it may also accomplish for apiculture Association and unity of action are the great mainsprings of power and progress in the world. I am pleased to know that the bee-keepers of this

to know that the bee-keepers of this country are awakening to this principle in marketing their products.
While in New York city last October 1 devoted one whole day investigating the honey market, and I must say that 1 was completely disgusted with the workings thereof. Not being personally acquainted with more than two of the firms handling honey, I had a splendid opportunity to investigate the facilities and the workings of many houses, by withholding my name and pleading ignorance. The honey of some of our leading apiarists was found in several different commission houses, and one different commission houses, and one apiarist in particular, who has probably written and said more upon this subject of "marketing honey" than any other one person, consigned his honey to more than one commission house, and the honey was not put up in a very marketable condition at that; the edges of the boxes being covered with propolis, and evidently no attempt had been made to remove it. One commission house sold this man's white honey for 12 cents, while another house was holding this same man's honey at 18 cents.

same man's honey at 18 cents.

One of the four honey honses in New York informed me that they received two-thirds of all the honey sent to that market. The proprietor of another honse told me that he handled most of the honey sent on commission to that city. Of course I saw their stock of honey, and truthfully say that both houses combined do not sell one-fourth the amount of honey sold by either of the other two honses. These men misrepresented their business, and if they misrepresented to me why wouldn't misrepresented to me why wouldn't they do the same to all other producers.

Then there are other commission men who receive now and then a small consignment of honey, and in almost every instance you will find that honey setting outside the door begging for a sale. After seeing all this and much more, I can say without fear of success ful contradiction, that at present there are but two firms in New York that have the facilities of handling our products, II. K. & F. B. Thurber & Co., and D. W. Quinby. Undoubtedly there is not another firm in this country that can place our boney on the markets of can place our honey on the markets of Europe to so good an advantage as can the Messrs. Thurber, while Mr. Quinby, who has been in the business for many years and has many customers, can place honey to good advantage and satisfactory to the consignor. Both these firms are making a specialty of our products, and they are the only ones. Go to New York with your honey; see where it is destined; look over the field before you, and I will venture to say you will corroborate all I have said.

Such being the case, what are we to years and has many customers, can

you will corroborate all I have said.
Such being the case, what are we to
do? We must have unity of action.
Let us concentrate what honey we put
on that market by sending to these two
houses. By so doing our honey will
command a higher price, sell faster, and
thereby insure us quicker and more
satisfactory returns. What will apply
to the New York market will hold good

for any of our markets. We must con-centrate our honey, and the quicker we do this the sooner we shall be able to sell our products for cash.

I will venture here to present another subject of great importance, and one that needs the co-operative effort of every apiarist. "Statistics of the agevery apparist. "Statistics of the aggregate production of both comb and extracted honey." With united action this can be accomplished. I would suggest that this association petition our national society, praying that the presi-dent thereof shall appoint reliable and willing vice-presidents in each and every State in the Union, whose duty it shall be to demand of each and every secretery of the different associations within his State to collect the correct statistics of the yield within his terri-tory; to report to the vice-president, who in turn shall report to the secretary of the National society, and he be required to cause the same to be published in each of the bee-journals no later than the first of September.

Every bee-keeper in making up his report should be very careful not to over-estimate his yield. In the past this has worked injury to our markets, many bee-keepers making a fictitions and an exaggerated report for fear that and an exaggerated report for fear that some neighboring apiarist may lead them in the amount of honey produced. This is all wrong and 1 trust we shall soon see the end. Remember that honey buyers keep their eyes upon all reports regarding the amount of honey produced in the country. That from these reports they fix the price to be paid; and when we go to sell our honey we are conneiled to face the reports. we are compelled to face the reports, When we are able to furnish corecct statistics, then we shall see the benefit.

statistics, fhen we shall see the benefit. Our larger markets are mostly supplied by the larger producers or specialists, while our local or smaller markets are left to the amateur or novice. To control these lesser lights will be hard work; but as long as they keep out of the larger markets they will do no great injury. They will be helping to increase the consumption. As soon as we get to a basis of buying and selling, smeanlators will control these small lots. speculators will control these small lots.

Our markets are also much injured by placing our products upon them in an unmarketable shape. Honey in the an unmarketable snape. Honey in the comb should be placed upon the market so as to call the attention, and tempt the consumer to purchase. To this end we should put up our comb honey in single comb sections, the combs being straight and evenly built and completely capped over. In regard to size of boxes, the demand seems to be settling down the demand seems to be settling down to about three sizes, viz: 4x4, 5x5 and 5x6 inches. In glazing, we should have the glass nicely cleaned and put on in good shape, being careful to first remove all propolis or wax adhering thereto. In grading and crating the apiarist should give his personal attention, that he may be positive as to destribe cheal large constraints and crating the apiarist should give his personal attention. ails should any question arise involving this part of the work. In grading it is well to make two grades white and two grades dark honey, putting all straight and perfect combs in the first grade, while those that are stained, unevenly built combs and not quite cupied over should be put in grade No. 2. In dark honey we frequently have combs that are honey we frequently have combs that are from 34 up white, being finished with dark honey. This should be graded black, No. 1, and all remaining combs should be classed as buckwheat. In crating, use only neat white crates holding 12 boxes, or if the boxes are small use crates weighing from 20 to 25 lbs. net. The honey must not be veneered and the crates should weigh even pounds, i. c., no halves or quarter pounds. We cannot be too particular in laying our boxes and crates neathy

pounds. We cannot be too particular in having our boxes and crates neatly made and placed on the market free from all dirt or stain or leakage.

In shipping, great care must be exercised. The crattes should be placed in the car with the combs running with the car, not over 6 crates high, setting close together at the side and end lose together at the side and end

Extracted honey is now classed as a staple article, therefore it is best to ship staple article, therefore it is best to sup-in bulk or barrels. But if designed for the retail trade it should be put up in small packages, such as small tin pails, or pint or quart glass fruit jars, some-thing that can be used after the honey is consumed.

## THOMAS C. NEWMAN.

EDITOR AND PROPRIETOR,

CHICAGO, H.L., APRIL 6, 1881.

## The Lessons of the Hour.

"Sweet are the uses of adversity," is a trite remark credited to Shakespeare, not only in America but throughout the world.

A gentleman from Minnesota assures us that in the southern part of that since the great storm of Oct. 14. Losses and privations have been the rule during the past 5 or 6 months. Fuel has been so scarce that in some places even the use as fuel; those sections cut off from communication have been deprived of tea, coffee and sugar, and the coffeemill has been made to serve the purpose of the flour-mill, to grind wheat for family use.

the timber, the principal sufferers being peach, soft maple, hickory and elm trees.

Birds, sheep, cattle and hogs have perished by thousands, being deprived of food and shelter and cut off from succor by the waves of death from the north and west, and the oft-repeated blizzard. Even mankind is no exception—untold numbers have been sacrificed upon the altar of the storm-king. Snow, hail, wind, blinding storm and blizzard-blast have united with poisoned air and miasmatic vapor to sweep men, women and children into the tomb, and is it any wonder that our pets-the bees—should suffer in common with all other forms of life?

But how difficult it is to discover the "sweet uses" of all this adversity! True, it may point out the more hardy kinds of trees, insects, birds and stock, to withstand the rigors of such seasons -upon the principle of "the survival of the fittest "-and it may teach men a valuable lesson on the necessity of securing more perfect ventilation, drainage and pure water.

When the unprecedented season bees. Perhaps there is a lesson to be learned here which we could learn in no other way. Close observation and profound study will no doubt be amply rewarded. "Let patience have her perfeet work."

Tr. Elnick Parmly, the genial Recording Secretary of the North American Bee-Keepers' Society, made us a very pleasant call last Thursday afternoon, on his return from a three weeks' tour through Colorado. We are glad to remarkably well after his extended trip, and his jovial good nature done much to banish the gloom occasioned by the was then falling.

## Is Bee-Keeping a Failure?

Now that the winter is drawing to a close, and the chilling blasts are becoming more fitful and spasmodic under the tardy but certain approach of spring, we begin to contemplate with an inward feeling of gratitication the genial sunshine and gentle showers with which Nature will awaken to life; the farstretching fields clothed in emerald green, the lawns and lanes with their grassy carpets, the air laden with the sweet perfume of the blossoms in garden and orchard, the trees in forest and grove animated with the feathered songwe believe. The winter of 1880-1 will sters whose little lives seem an incarnalong be known as one of the most severe tion of happy melody-all these will in its nature and direful in its effects, combine to help us forget the dreary hours of the past, and with keener zest enjoy the future. But how many will miss the cheerful hum of the myriads of toiling bees, whose flitting wings State fully 10 feet of snow has fallen were wont to bear them from flower to flower, where they gathered nectar fit for a bananet of the gods.

We can scarcely wonder that many have become discouraged and almost "liberty pole" has been sacrificed for doubt whether bee-keeping pays, when they think of the meager honey yields of two successive summers, and view the untenanted hives and soiled combs which are left as the sequel to their cherished hopes for the future. However, none should be too hasty in pass-Heavy sleet storms have destroyed ing judgment. With the hives and combs already provided, more than onehalf the original investment is saved, and with a propitious season for the present, our losses will be made good with a credit in our favor on the balance sheet. We cannot expect bee-keeping to be profitable every season, any more than any other special branch of industry which is dependent upon natural causes, but we can with forethought, industry and systematic perseverance. make it as reliable as any other, and now that many will be compelled to begin anew (or comparatively so), we suggest that they begin aright. It will not be a guaranty of success that they use the best hive, nor that they have an abundance of bees; a familiarity with all the recognized authorities and a mind crammed with theories, will often fail; the industrious brown bee will seek in vain, the gold-banded Italian bee will tire in its flight, and even Apis dorsata will view its stores with dismay, if there be no nectar-laden bloom from which to gather.

Now is the time to invest for the future. Every dollar judicionsly paid out for seeds of honey plants will bear compound interest—will be "bread cast shall have passed, let us try to fathom upon the waters." The traditional these deep lessons in respect to our two or three weeks of honey-flow can, with a trifling expenditure, be made to last more than as many months; a succession of bloom can be secured, so that should northerly winds or wet weather prevail for a time, it would not carry dismay to our hopes and starvation to our bees. If, as we hope and confidently believe, the present should prove an unparalleled honey season, it will ameliorate the only tenable objection to melilot or sweet clover, which is that it blooms but little or none the first season: and we can well wait till another season for we can well wait till another season for our "sweet" reward from it. There are many other plants which we believe would repay cultivation in honey alone, but not one that will bear comparison with this Esau of the vegetable kingdom. Never was a better time to start dom. Never was a better time to start. say the Doctor was looking and feeling our "sweet" reward from it. There drizzling and monotonous snow which with this Esau of the vegetable king-

in right than now, and never can we truthfully say bee-keeping is more hazardous than other industries, or less remunerative, until we have made some provision against natural failures and seasonable disasters. Every bee-keeper should, in justice to himself, test this matter of planting on a sufficiently extensive scale to satisfy himself. We feel confident of the verdict.

## Law Against Adulteration in N. Y.

We have received the following copy of the bill against adulteration, referred to on page 92 of the BEE JOURNAL for March 23. Mr. L. C. Root remarks: The readers of the BEE JOURNAL are. no doubt, interested in the progress being made regarding the bill upon which action was taken at the late session of the Northeastern Bee-keeper's Association. The subject is one of marked interest to bee-keepers in general. I send you a copy of the bill, which may be of interest and which shows the progress thus far made.

Assembly of New York. — Intro-duced by Mr. Root—read twice and referred to the committee on trade and manufactures—reported favora-bly from said committee and com-mitted to the committee of the whole.

An Acr, To prevent fraud in the adulteration of sugars, syrups, molasses and honey.

The people of the State of New York, represented in Senate and Assembly, do enact as follows:

Sec. 1. Any person, company or corporation engaged in the manufacture, refining or mixing of sugars, syrups, molasses or honey for sale, who shall mix the same with glucose or grape sugar or any other article of adulgrape sugar or any other article of adulteration, shall, before selling or offering the same for sale, cause to be marked on the cask or package in which it is contained, the percentage of glucose or adulteration therein contained, such mark or label shall be in plain Roman capital latters not less than 1, each in capital letters, not less than 12 each in dimensions, in black ink or paint, and on the upper and most conspicuous part of the eask or package.

§ 2. Any person, company or corporation who shall sell or offer to sell such mixed or adulterated sugars, syrups, honey or molasses containing glucose, grape sugar, or any articles of adulteration, shall expose or sell the same in or from the original packages in which it was consigned from the manufacturer or mixer to the same, and shall be plainly and conspicuously marked or labeled as required in the first section of this cot. of this act.

2 3. Any person who shall violate the provisions of this act shall be deemed guilty of a misdemeanor and on conviction thereof shall be liable to a fine of not less than \$10 nor more than \$200, or to imprisonment in the county jail for not more than 60 days, or both line and imprisonment in the discretion of the

This act shall take effect on the first day of June, 1881.

Vennor's Predictions for April.

So remarkable have his predictions been fulfilled in the past that we hope we shall not be disappointed in his predictions for May weather during at least a part of this month. The following are his probabilities for April:

There will be sharp frost in the beginning of April, with a snowfall on the 4th or 5th, but the spring will open favorably, and everything will be pretty well advanced by April 15. Floods may be expected in Chicago about the first week in April, with high winds also prevailing in the early part of the month. Snow-falls are probable about April 5. Navigation is likely to open on Lake Ontario about April 7. Navigation is likely to open

April 5. Navigation is likely to open on Lake Ontario about April 7.

The St. Lawrence will be open about the 9th or 11th, and the first steamship will probably arrive about the 17th or 18th. The weather will be very stormy in the Lower Provinces about the 20th, with very high water prevailing, but in the West, April will be a dry month. There will be warm weather just following the 20th, ending in thunderstorms on the 24th and 25th. Snowstorms are probable in the far West on the 25th and 26th, and snow-falls are not unlikely to occur in England at the close of the month. The month will end wet and cold, but, on the whole, will be like a May month.

Two Queens in a llive.-Mr. Fradenburg says: " I think I can throw a new ray of light on this subject, which is now-a-days attracting some attention among bee-keepers. I have come to the conclusion that there are but just two causes or conditions in which two laying queens will be found in a hive at once-the first is the superseding of an old and failing queen, in which case each queen seems to have a sort of reverence for the other; the second condition is that the bees in one part of the hive do not know at all times what is going on in another part of the hive. This assertion may raise a storm of opposition among the fraternity, but I believe I have the positive evidence to support it."

We have received a very nice specimen of thin foundation for surplus boxes, made on the Root Mill, from G. W. Stanley, Wyoming, N. Y.

This issue of the BEE JOURNAL, the first in the month, goes to all the subscribers of the Weekly, Monthly and Semi-Monthly. Should any of the latter wish to change to the Weekly, they can do so at any time, by paying the difference.

We can supply but a few more of the back numbers to new subscribers. If any want them, they must be sent for

California has had its floods, and now the Northwest is having a severe experience in the same line. According to Vennor our turn is next. Let all be watchful, and prepare in time, if possible, to avoid loss.

Single copies of the JOURNAL are sent postage paid for 5 cents each.

Constitutions and By-Laws for ocal Associations \$2 per 100. The name of the Association printed in the blanks for 50 cents extra.

Correction.—In the BEE JOURNAL for March 16, page 85, the number of my colonies is given as 25; it should be 85. So far as I can learn they are in good condition. I winter them in the cellar. I have been handling bees for 6 years. Osage is a growing city, and ceuar. I have been handing bees for 6 years. Osage is a growing city, and will consume all the honey produced in this locality. There are about 500 colonies of bees in Mitchell County, and I will do my share in supplying the market with honey. Chas. Follett. Osage, Iowa, March 21, 1881.

Good Enough.—My bees wintered well. I only lost one out of 92 colonies. Some have lost all they had; others 23. etc. The spring is backward. As yet we have had but few days that bees could fly.

Union. Ky., March 22, 1881.

Using Old Combs.—Is it not dangerous use combs with dead brood in from defunct colonies? Is there not danger of getting foul brood started? I have a good many of them, and I am undecided whether to melt them up or save The losses here have been fearthem. The losses here have been fear-ful. I do not think there are 10 live colonies in Dixon outside of my apiary, and I have lost 13. Those lost were packed in dry chaff, as Prof. Cook's Mannal directs, in Langstroth and Simplicity hives, while Root's chaff hive has come out ahead, only 2 or 3 hives of this kind have failed out of about 20 this kind have failed, out of about 30 chaff hivesin use. There were as many as 10 or 12 different apiaries in and near Dixon, and I can count 8 of them now that are all dead; the most of them were small, containing from 6 to 30 colonies each. And the end is not yet. Those yet alive may die soon unless spring opens at once.

B. F. PRATT. opens at once. B. F. Dixon, Ill., March 27, 1881.

IIt is hardly possible there is a great deal of dead brood in the combs to be removed. We should not hesitate, if the brood is dry and shrunken, to place the combs in strong colonies; but if the brood is putrid and ropy, and sticks to the cells, we would not wish to use them, as it is easy to imagine the possibility of foul brood or other diseases arising therefrom. If, as we suspect, your combs are filled with starved bees, you can easily remove them by adopting the plan recommended in the Weekly BEE JOURNAL of March 16, page 86. Mr. H. T. Collins gives his method in this number of the JOURNAL.—Ed.]

Never Gire Up.—Bees are nearly all dead. A long winter is the cause, of course. "Never give up" is and must be our motto, but we must learn not to venture too far without experience to back us.

N. J. Longsdon. back us. Byron, Ill., March 26, 1881.

Good Prospect.-There is every prosgeod Prospect.—Inere is every prospect of a prosperous season now, as we are having rain enough, and I never saw bees in better condition. I commenced on the 3d of March to divide colonies, rear queens, &c. I have my menced on the 3d of March to divide colonies, rear queens, &c. I have my hives nearly completed for the season's operations. There is quite a contrast between northern Iowa and southern Cal. for bee-keeping. I commenced the last season with 48 colonies in very page condition and this good I commenced. poor condition, and this season I start with 108 in extra good condition; in fact, the poorest colony I have is in as good condition as the best was last season at the same time.

Elisha Gallup. Santa Paula, Cal., March 18, 1881.

Spring Come at Last.—The weather is spring-like here, and has been since March came in. The snow has all disappeared, and our roads are dry and dnsty. As I write the blue birds and robins are singing merrily.

HENRY ALLEY.

HENRY ALLEY. Wenham, Mass., March 23, 1881.

Come Gentle Spring.-1 have 60 colonies in the cellar; they are in poor condition and will all die if Vennor does not give us fine weather soon, so that the bees can have a flight. They were all right March 1st.—I like the Weekly much better than the Monthly.

W.M. C. GRAY.

Pre-emption, Ill., March 21, 1881.

Bees All Right.—I have lost 2 colonies out of 16, and the remaining 14 are strong. I had them packed in buckout of 16, and the remaining strong. I had them packed in buck-wheat chaff, which is considered the best packing we can get. I have wintered for 4 years with it, and had success. In the winter of 1877 and 1878 I had 45 colonies packed in kiln-dried shavings and wheat chaff; but 4 were packed in buckwheat chaff and those 4 lived; the rest died. There was a very heavy loss around here among those that were left unpacked. I am well pleased with the Weekly BEE JOURNAL. W. S. BAIR. Journal. W. S. BA Rollersville, O., March 24, 1881.

Lost 6 out of 100 Colonies. - The snow is all gone now and our bees have had several flights. On the 16th they gathered some pollen; but this has been the most disastrous winter among been the most disastrous winter among bees in Maryland for many years; 75 per cent of all the bees in north Md. are dead. We had a very poor honey season last year, except 5 weeks during the first crop of red clover, which ended about the 1st of July; and after that but little honey was gathered. The bulk of the loss was from neglect or starvation. As I had a fair demand for queens and I was breeding for improvement I kept up the gueen breeding unment I kept up the queen breeding un-til the last of Oct., and my bees were in poor condition for an ordinary win-ter; much more for such a one as we have just passed through. I have lost 6 colonies at home, that starved; I have 96 left in fair condition. I wintered in a cellar expressly arranged for the pura cenar expressly arranged for the pur-pose; it is perfectly dark, and the tem-perature in this place was kept all through the winter at 46° and 474. All those that wintered in cellars fared he best. I am much pleased with the Weekly. I should lose a friend were I Weekly. to be deprived of it. I wish it every success. S. VALENTINE. Double Pipe Creek, Md., March 22.

Vexed and Perplexed. — When I go into my bee lot and look around I am vexed over the situation and perplexed to know what to do with my hives and combs. I put into winter quarters 16 colonies (all blacks) and now have one, very weak. I have a lot of nice, wellmade and painted hives on hand, and a lot of combs. As I have never handled Italian bees, and have concluded to purchase, and I hear they are larger than the blacks, will you please answer these 2 questions in the BEE JOURNAL:

Are comb cells of the black bee too. small for the Italians to raise brood in? Will it not cramp them in size? Will it be safe to feed the thin uncapped honey that has caused dysentery to other bees? The bees in this vicinity other bees! The bees in this storm, are all dead. Success to the Bee Jour-Mansfield, Ind.

[The difference in size of cells is not perceptible. If bees are flying freely, you can feed the thin honey with impunity.-Ed.

Ventilation.—I have met 14 different persons in the last few days that had, last Nov.,168 colonies of bees altogether; now they have in the aggregate 57 living; these were mostly in frame hives, ing; these were mostly in frame lives, on the summer stands, and left to care for themselves. Nearly all died with plenty of honey to have carried them through. This, I think, will be about the average loss in the counties of Champaign, Piatt and Moultrie, in this State. Why, H. Beekwith, started in Champaign, Piatt and Moultrie, in this State. Wm. II. Beekwith started in the winter with 18 colonies in Langstroth and box hives, with plenty of bees and honey in each hive. The hives were very poorly made, being open at the corners, with a board laid on top to keep the rain or snow from falling directly into the hive. Nearly all of them set on blocks from one to two inches from the bottom board; they were ven-

dead colony. Some 5 or 10 are considerably diseased, and a few are almost sure to be found queenless. I expect to lose from 5 to 15 between this and honey harvest. Bees generally have wintered very poorly in this section. From ½ to ¾ of all the bees put in winter quarters last fall, have died. I winter entirely in chaff hives, and from what I hear I judge that that method of wintering has succeeded better than any other during this past winter.

O. O. POPPLETON.

Williamstown, Iowa, March 25, 1881.

Orchard Apiary.—The following is my report for 1880; My bees came through very strong in spring, and bred rapidly, and were in excellent condition to take advantage of fruit bloom, which lasted about a week, during which time they filled the hives well with honey, and it is well that they did, for raspand it is well that they did, for raspherry and white clover proved a total failure here, on account of bad weather in June. My surplus all came from basswood, which produced well for about 10 days. Notwithstanding the poor season, and it was the poorest we we have had, I realized a profit of over SS per colony; but went into winter appropriate the resulting the properties of good states of the season of quarters strong and with plenty of good wholesome stores. E. A. Th Coleraine, Mass., Feb. 1, 1881. E. A. Thomas.

Loss in Cellars, etc.—I put 95 colonies in the cellar on Nov. 15. I took them out yesterday, which was the first day they could fly with safety since about the first of last Nov. Loss 4 (one probably queenless when put in, and 3 starved). A few are weak, but most of them are in good condition. This has been a very hard winter on bees that were not properly cared for. Those left out are nearly all dead, as far as heard from. A good many have died in cellars and special repositories, for want of a knowledge of the proper conditions for success. I like the Journal very much.

J. E. Hunter.

Wyoming, Iowa. March 25, 1881.

Blasted Hopes.—For the first time, I enroll myself in the army of "blasted hopes." My 150 colonies of bees are (all but one) among the things that were. I had no honey from them last season, or at least none but what I fed back in the fall, and a good many were entirely destitute, so that I broke them up. Some had a little honey and I gave that to those that had a little more, and still had 150 left. Winter set in early, about the middle of Nov., before I had packed any of them. I waited for milder any of them. I waited for milder weather so that I could pack them, but that did not come until the 6th of March. ever a day did my bees have a fly un-Never a day did my bees have a fly until then; and then I had but one colony fly, and I hoped they would come through all right in my double hives, but they did not. Most of them had plenty of honey. All of those having honey had brood and some of them young bees; such had soiled the combs. The one that is alive is strong and has plenty of brood. I thought that bees did not commence to raise brood until a warm spell, but it seems I was mis-

tilated better than any bees I have seen this season; he has 16 colonies to day, alive, and apparently ingood condition. Perhaps there is more in ventilation than chaff hives or cellars. Will some one please rise and explain?

S. Goodrich.

Urbana, Ill., March 23, 1881.

Bees Confined 5 Months.—Yesterday my 115 colonies of bees had their first flight since the last week in Oct., having been confined to their hives 5 months, lacking 2 or 3 days only. This is a month longer than I have ever had them confined to the hive without a flight, during the past 12 years, and to my very great satisfaction as well as astonishment, I do not find a single dead colony. Some 5 or 10 are considerably diseased, and a few are almost sure to be found queenless. Lexpect to lose from 5 to 15 between this and honey Kalamazoo, Mich., March 12, 1881.

> The Ontlook Encouraging.—The loss in wintering has been very heavy in this county during the past cold winter. In one apiary near me, in Langstroth hives, only 5 are now alive out of 100 last Oct. My home apiary of 175 colonies last Oct., mostly in closed-end Quinhy-frame hives, wintered on summer stands packed with fine straw and chaff, now numbers only 115. The loss has been much the heaviest in open end frames, especially so in metal corner frames. Out of 78 in such frame hives only 2 colonies are left. Last year was frames. Out of 78 m such frame hives only 2 colonies are left. Last year was the poorest season I have had in 12 years; I had but one natural swarm during the season. White clover was a failure; there is but little basswood near here. By feeding I kept my bees in good applicition for the full by years. near here. By feeding I kept my bees in good condition for the fall harvest; in good condition for the fall harvest; smart weed furnished a very little; Spanish needle (the best honey plant in this section) was a total failure; this is the 2d year in 12 that it has failed. I had one apiary near the Illinois river which contained 120 colonies last spring, in this but had a second way to the in Quinby hives. The early part of the season was poor, but I had during the season 21 natural swarms and over 3000 lbs. of section honey for sale, with a surplus of 3000 lbs. in brood frames; more than enough to winter them, which I brought to my home apiary. The above harvest was wholly from smart weed, which was grown on over smart weed, which was grown on over-flow land near the Mississippi and Illi-nois rivers. The loss in this apiary will not exceed 10 from all causes. All are strong and booming. The soft ma-ples are now in bloom; every fair day the bees are carrying in pollen and a very little honey; the elm will soon be in bloom furnishing an abundance of pollen for rainful queen reging. With pollen for rapid queen rearing. With favorable weather I expect a spring harvest from the willow privet bush and red haw; the honey from these is very Your hopeful outlook for the coming season is very cheering. The Weekly is both a pleasure and a necessity with me.
>
> A. T. WILLIAMS. St. Charles, Mo., March 24, 1881.

Severe Winter, but Bees All Right,— This has been the most severe winter experienced by the oldest inhabitant in Ky. I have 14 colonies well packed in chaff, on their summer stands; 3 in the star chaff hive, 9 in the simplicity with tight bottom and portico, and 2 in the simplicity hive. Banked each of them on 3 sides with snow; 12 faced south, 2 north, with no winter passages; used the enameled cloth contrary to friend Muth's advice. I packed on each side of those in single-wall hives with loose chaff, also on the top. I had from 3 to 7 frames in each hive. All wintered equally well, and to-day the queens are doing their duty nobly, shut in on from 2 to 2 frames, and grayded with bees 2 to 3 frames, and crowded with bees. I think the chaff hive unnecessary for this climate, but it is necessary to pack them well with an absorbent in order to bring them safely through our generally changeable winters. Success to the Weekly; it is growing in interest from week to week, and its coming is anxionsly longed for. C. H. Dean.

Mortonsville, Ky., March 18, 1881.

Winter Bee House.—My bees have wintered splendidly in my winter bee house.

L. CARSON. Frederick, O., March 24, 1881.

Bees Wintered Well.—Bees on the summer stands without protection have summer stands without protection have wintered poorly in this vicinity. I have fifty colonies in Quinby hives, packed in out chaff and cut straw, that have all wintered well so far. Most of the bees in this vicinity are in box hives, and nearly 12 of them are dead as far as heard from.

E. DEUEL. heard from. E. DEUEL.
Portlandville, N. Y., March 24, 1881.

Bees in fair Condition.—My bees are in a fair condition, on the summer stands. I put into winter quarters 66 colonies; lost 3 and bought 14, making 75 in fair condition. Owing to old age and poor health I intend to sell my bees, although 1 regret it very much. Last year was a very poor one for honey. I obtained about 600 lbs. of comb honey, which I sold for 15 cts. a lb., and I had one swarm. I like the Weekly BEE JOURNAL very much. I had one colony of least swarm out on the 15th of this JOURNAL very much. I had one colony of bees swarm out on the 15th of this month; they flew around about half an hour and then went back into the hive again. I examined them on the 17th and found the colony strong, with combs all dry and nice, and about 25 lbs. of honey, some pollen, with eggs and brood in all stages. They are now satisfied.

Corydon Ky, March 25, 1881 Corydon, Ky., March 25, 1881

The Survival of the Fittest.—Another blizzard struck us yesterday; the weather is not so cold, but the high winds ther is not so cold, but the high winds and heavy fall of snow make it more disagreeable than any day of the cold zero weather. Bees will get another set-back by their brood chilling. Those that come out in good condition this spring can be considered tough citizens, and no mistake. Jos. M. Brooks. Columbus, Ind., March 30, 1881.

Half of the Bees Dead .- There is a loss of more than one-half of the bees in this county. I am well pleased with the Weekly BEE JOURNAL.

W. A. HERRON.

Indianola, Iowa, March 28, 1881.

Wintered Without Loss,—1 believe 1 am the only one in this county that has not lost more or less bees this winter. not lost more or less bees this winter. My bees were all transferred from lox hives last fall, their stores taken away, and they were fed on syrup. They have wintered without any loss of bees. I have bought of Mr. Muth, of Cincinnati, some extracted basswood honey, and shall dilute it with sugar syrup and feed this spring. My bees all have more or less brood now. W. T. CLARY. Clarysville, Ky., March 29, 1881.

Wintered Safely.—Bees are dying very rapidly in this section of country. I have 18 colonies; 2 are weak, but I have lost none so far. I bought a Cyprian queen from a firm in the East. She wintered all right, but her workers are hybrid Italians. I lost one last fall by foul brood. I am much pleased with the Weekly BEE JOURNAL.

WM. 11. GARHIAN.
Northumberland, Pa., March 28, 1881.

Chaff Did Not Save the Bees.—The bees in this vicinity are mostly dead. Chaff did not save them from the effects of the past severe winter.

L. Hubbard.
Waldron, Mich., March 25, 1881.

Wintered in Chaff.—Three-fourths of the bees in this neighborhood are dead. the bees in this heighbourhood are dead. I packed mine with chaff on the summer stands, and they came out nice and strong. I am a beginner, and derive much benefit from the BEE JOURNAL. which is a welcome visitor.

EVAN B. HADLEY.

Deming, Ind., March 29, 1881,

Eleven Swarms from One Colony. commenced the last spring with 13 Italian and 4 black colonies, and in the Italian and 4 black colonies, and in the fall I had 70; lost 6 in wintering by heing queenless. I have sold 4, and now have 60 doing well. I had 11 swarms from one colony and its increase, besides 50 lbs. of honey. The Bee Lournal is the bee paper, and I wish it success.

Leesville, Texas, March 14, 1881.

A Visit Every Week, Very Pleasant.— My bees have been at work on the soft maple for the past week. I commenced maple for the past week. I commenced the winter with 31 colonies; I now have 21; many of them are very strong; some died with plenty of honey in their hives. Last season was a poor one, giving no surplus. I think there will be a heavy loss of bees here. I thought I would not like the Weekly Bee Journal as well as the monthly, but I would not avelenged it now for any monthly. not exchange it now for any monthly, because I can hear from my bee-keeping friends every week. I wish it great N. Davis.

Emporia, Kan., March 28, 1881.

Buds are Swelling; Spring is Coming.

—By the JOURNAL I notice that the winter has been a disastrous one to bees. It must be hard to report a loss of <sup>a</sup><sub>1</sub>; and some of the reports even say— "all dead." I am afraid that some of the bee-keepers in this section can say ditto to these reports. The loss around the bee-keepers in this section can say ditto to these reports. The loss around here is greater than there is any need of, on account of the carelessness of farmers in preparing their bees for winter; some of them leave them out on the summer stands without any protection relative materials. the summer stands without any protection whatever, and of course the result is plain. I have wintered mine in the cellar for the past 2 seasons without any loss, except one that starved this winter; and I am to blame for that in not knowing their condition when I put them in the cellar. I think that now all fear of loss is past, for my bees are doing as well as could be desired. They are breeding considerably, and are all bright and healthy. The snow is going off slowly, at last, and we may look for spring soon. The maple trees are full of swelling buds—it is too early to say anything about fruit bloom; I don't know whether it is killed or not. White clover looks well where the snew White clover looks well where the snew is off, and it promises well for the comng season. HARRY G. BURNET. Blairstown, Iowa, March 26, 1881.

Bees About All Dead.—I put my bees into winter quarters in the Mitchell hive, packed with clover chaff at each end of the hive about 6 inches thick, and over the top with cushions with the same, about 4 inches thick, all on the summer stands. My loss is now about 2 per cent. The snow is now from 12 to 15 inches deep; this does not look yery encouraging: the bees in this trom 12 to 15 linenes deep; this does not look very encounaging; the bees in this part of the country are about all dead. I like the Journal much better as a Weekly than pefore; it gives us freshnews.

Reynoldsburg, O., March 30, 1881.

**Donble-Walled Hives.**—A large proportion of bees have died in this vicinity this winter. I have lost 6 colonies out of 16. I am using Ilill's double-walled winter bee hive. I lost none wintered in these hives, but every one in Leaguertath, bives died it I wintered. in Langstroth hives died. I wintered on summer stands and one hive had as much protection as another. I feel sure I should have saved all if I had used the double-walled hive; those that the double-walled hive; those that died had honey enough in the hive to have wintered them through, if they could have got at it. My bees are carrying pollen every day they can be out.

J. R. WILCOX.

Utica, Ind., March 29, 1881.

Losses in Wintering.—Having seen Losses in Wintering.—Having seen no report from this vicinity, I have taken some pains to ascertain the extent of the losses of the bee-men of this part of Wayne county, Ind. I have reports (some of them indirectly) from 34. Ten report a total loss; 8, 90 per cent.; 6, 80 per cent.; the others from 33 to 25 per cent. The average loss of colonies will probably be 80 per cent, and those colonies which survive are very much reduced in numbers. Most of them were left unprotected on the very finent reduced in miniors. Most of them were left unprotected on the summer stands. I find that those that were taken into the cellar before the severe cold of November, came through with small loss, while those taken in afterice had accumulated in the hive, fared the werst of all. I am an advocate of cellar wintering, having never lost a colony until the present winter, letters, procure 1 am convinced that dysentery (the one such than silver.

great cause of our loss) could have been much mitigated by keeping an even temperature, which cannot be done out-or-doors, and had we removed their unsealed, poor food and fed them caudy instead, our reports would have been different. Two colonies thus treated by me came through in good condition. My bees gathered pollen and honey yesterday from the willow. Maple will

be in bloom in a few days.

## CLUBBING LIST.

We supply the Weekly American Bee Journal and any of the following periodicals, for 1881, at the prices quoted in the last column of figures. The first column gives the regular price of both:

The Weekly Bee Journal (T. G. Newman) \$2.00 and Gleaningsin Bee-Culture (A.I.Root) 3 (O. 2.75 Bee-Keepers' Exchange (J. H.Nethis), 2 (5), 300 2.86 Bee-Keepers' Exchange (J. H.Nethis), 2 (5), 2.75 Bee-Keepers' Exchange (J. H.Nethis), 2 (5), 2.76 Bee-Keepers' Instructor (W. Thomas) 2 (0), 2.35 Bee-Keepers' Instructor (W. Thomas) 2 (0), 2.35 The Gabove-named papers, 5, 5, 5, 60 Prof. Cook's Manual dound in cloth 3 (2), 32, 3 (0), 25 For Seni-monthly Bee Journal, 81,00 less. For Semi-monthly Bee Journal, \$1.00 less. For Monthly Bee Journal, \$1.50 less.

# Honey and Beeswax Market.

BUYERS' QUOTATIONS.

HONEY. The market is plentifully supplied with boney, and sales are slow at weak, casy prices. Quotable at 186-20c, for strictly choice white comb in 1 and 2 lb, boxes; at 146-15c, for fair to good in large packages, and at 106-10c, for common dark-colored and broken lots. Extracted, 86-10c.

BEESWAX.—Choice yellow, 296-25c; dark, 15@17.

NEW YORK,

HONEY.—Best white comb honey, small near packages, 140 lbc.; fair do., 140 lbc.; dark do., 11612; large boxes sell for about 2c, under above. White extracted, 9g lbc.; dark, 168c.; southern strained.

BEESWAX.—Prime quality, 20@25c.

CINCINNATI.

HONEY.—The market for extracted clover honey good, at 80010c. Comb honey is of slow sale at 16c. for the best, BEESWAX-18@22c. C. F. MUTH.

SAN FRANCISCO.

SAN FRANCISCO.

HONEY.—The "Vigilant" takes can cases to Liverpool. There is a sightly improved feeling consequent upon a little more inquiry, but prices show no maternal appreciation. Discouraging reports are received from the southern part of the State, as to the prospects of the coming crop, but other sections give promise of an abundant yield. With a good supply yet on the market, prices are not up to be buoyant until the anticipated failure is more fully settled. We quote white could, 12e Hz, dark to good, 3e Ht. Extracted, choice to extra white, 5½600½c.; dark and candided, 5eolgie.

candred, 56 (54g).
BEESWAX—226 (224g)., as to color.
STEARNS & SUITH, 423 Front Street.
San Francisco, Cal., March 11, 1881.

A Smooth Complexion can be had by every lady who will use Parker's Ginger Tonic. For promptly regulating the liver and kidneys and purifying the blood there is nothing like it, and this is the reason why it so quickly removes pimples and gives a rosy bloom to the cheek. See notice.

🕼 We have prepared Ribbon Badges for bee-keepers, on which are printed a large bee in gold. Price 10 cents each, or \$8.00 per hundred.

Notices and advertisements intended for the Weekly BEE JOURNAL must reach this office by Friday of the week previous.

Instead of sending silver money in letters, procure 1, 2 or 3 cent stamps. We can use them, and it is safer to send

The Michigan Bee-Keepers' Association will convene in Pioneer Rooms of the State Capitol at Lansing, May 5. The following is the programme:

Regular order of business.
Annual address by Pres. W. J. Ashwortb.
Address by T. G. Newman, editor of American Bee
Journal; subject. Rise, Progress, Present Condition
and Future Prospects of American Aplculture.
Essay-Protitable extent of bee-keeping, by James
Heddon, howagiac.
Essay-Requisites of an Apiary, by H. A. Burch,
South Hayen.
Essay-Some important facts in bee-keeping, by
Prof. A. J. Cook, Michigan Agricultural College.
Discussions and remarks,

Prof. A. J. Cook, Michigan Agricultural College. Hiscussions and remarks, Examination of exhibits, All exhibitors of supplies are requested to send snapples to the Secretary, with prices and descriptions attached, and all transportation charges must be prepaid by the exhibitors, GEO, L. PERRY, Sc.

Programme of the Northwestern Bee-Keepers' Union, to be held at Has-tings, Minn., May 17, 1881:

1.—Address of Welcome, by J. N. Searls.
2.—Reports of committees.
3.—Reports from all-number, kind and condition

3.—Reports from all—number, kind and condition of bees.
4.—A paper by Pres. A. Tidball, on honey-producing plants and flowers.
5.—A paper by Dr. P. Barton, of St. Paul, on honey as food and medicine.
6.—A planty culture and our falra, by Hon. William Avery, of St. Croix Falls, Wis.
7.—A paper on sales of boney, by F. B. Dorotby, of Taylor's Falls, Minn.
8.—A paper on sales of boney, by L. Day, of Farmington.

S.—A paper on wintering bees, by L. Day, of Farmington.

19.—Progressive bee-culture, by J. G. Teter,
The above subjects will be open for discussion. In
addition to the above, the following subjects are suggested:

gested:
1.—Essential properties of a good bee hive.
2.—How to prevent and cure foul brood,
3.—How to prevent spring dwindling,
4.—Comb Foundation, with dividing and natural swarming.
Appointment of committees.
Election of officers. Adjournment,
187 All bee keepers are cordially invited. Entertainment free.
F. B. DOROTHY, Sec.

The Northern Indiana Bee-keepers Association will hold their regular meeting at the Court House, at Valparaiso, Ind., April 7th, 1881, at 2 o'clock p. m., for the election of officers, and for the transaction of any other business that may come before the meeting.

J. B. Decrow, Sec.

The North Western Wisconsin Bee-keepers Association will meet at Germania Hall, LaCrosse, Wis., on Tuesday, May 10, at 10 a. m. All interested in bee-keeping are requested to be present. L. II. Pammel, Jr., Sec.

The Semi-Annual meeting of the Champlain Valley Bee-Keepers' Association will be held at Bristol, Addison ciation will be new .... Co., Vt., May 19, 1881. T. Brookins, Sec.

The next meeting of the N. W. Illinois and S. W. Wisconsin Bee-Keepers' Association, will be held at H. W. Lee's, 2 miles n.w. of Pecatonica, Winnebago county, Ills., on the 17th of May, 1881.

J. STEWART, Sec.

COn account of unfavorable weather the convention at Monroe Centre, lll., met on Feb. 8, and there being but few present, adjourned to the same place on March 29, 1881.

A. RICE, Pres.

The Texas Bee-Keepers' Association will hold their third annual Convention at Judge W. H. Andrews' apiary, in McKinney, Collin Co., Texas, on the 12th and 13th days of May, 1881.

WM. R. HOWARD, Sec.,
Kingston, Hunt Co., Texas.

Gray Hairs Are Honorable but their premature appearance is annoying. Parker's Hair Balsam is popular for cleanliness and promptly restoring the youthful color.

BEE JOURNAL will be sent free to any names that may be sent in. Any one intending to get up a club can have sample copies sent to the persons they desire to interview, by sending the names to this office. names to this office.

🕼 It would save us much trouble, if all would save us much trouble, if all would be particular to give their P.O. address and name, when writing to this office. We have several letters (some inclosing money) that have no name. Many others having no Postoffice, County or State. Also, if you live near one postoffice and get your mail at another, be sure to give the address we have on our list.

# Books for Bee-Keepers.

Cook's Moninal of the Aplary. Entirely rewritten, greatly enlarged and eleganity illustrated, and is fully up with the times on overy conceivable subject that interests the upinrist. It is not only instructive, but interestly interesting and thoroughly practical. The look is a masterly production, and one that no bee-keeper, however finited his means, can afford to do without. Cloth, \$1,254 paper covers, \$1.00, postpaid. For dozen, by express, etch, \$12; paper, \$250.

Quinby's New Ree-Keeping, by L.C. Root— The author has treated the subject of bee-keeping in a minner that cannot fail to interest all. Its style is plant and foreible, making all its readers sensible of the fact that the author is really the master of the subject. Price, \$1.50.

Novice's A B Coffice-Culture, by A. I. Root. This embraces 'everything pertaining to the care of the honey-tee," and is valuable to beginners and those more advanced. Cloth, \$1.25; paper, \$1.00.

King's Bec-Keepers' Text-Hook, by King. - This edition is revised and brought do the present time. Cloth, \$1.00; paper, 75c.

Langstroth on the Hive and Honey Hee This is a standard scientific work. Price, \$2.00.

Blessed Bees, by John Allen.—A romance of her-keeping, full of practical information and contagions enthusiasm. Cloth, \$1.00.

Recevilling; to Successful Management of the Apiary, by Thomas G. Newman.—This pampible embraces the following subjects: The Location of the Apiary—Honey Plants—Queen Reuring—Feeding—Swarming—Dividing—Transfering—Intination of the Apiary—Honey Plants—Queen Reuring—Feeding—Swarming—Dividing—Transfering—Intination of Propering Honey for Market, etc. It is published in English and German. Price for either edition, 40 cents, postpaid, or \$3.00 per dozen.

Food Adulteration; What we ent and should not eat. This book should be in every family, where it ought to create a sentiment ngainst the adulteration of tood products, and demand a law to protect consumers against the many bealth-destroying adulterations offered as food. 200 pages. Paper, 50c.

The Dzierzon Theory; presents the fundamental principles of bee-culture, and furnishes a condensed statement of the facts and arguments by which they are demonstrated. Price, 15 cents.

which they are demonstrated. Price, 15 cents.

Haney, as Food and Medletne, by Thomas G.
Newman.—This is a pumphlet of 24 pages, disconsing
upon the Ancient History of Bees and Honey; the
nature, quality, sources, and preparation of Honey
for the Market; Honey as an article of food, giving
recipes for making Honey Cakes, Cookies, Puddhas,
Foam, Wines, &c.; and Honey as Medicine, followed
by many useful Recipes. It is intended for consumers, and should be scattered by thousands all over
the country, and thus assist in creating a demand for
honey. Published in English and German. Price
for either edition, 6c.; per dozen, 50c.

Wintering Rees.—This pamphlet contains all the Prize Essays on this important subject, that were read before the Centennial Bee-Keepers' Associa-tion. The Prize +25 in gold—wis awarded to Prof. Cook's Essay, which is given in full. Price, 10c.

The Mive I Use Being a description of the hive used by G. M. Doolittle. Price, 5c.

Extracted Honey; Harvesting, Handling and Marketing.—A 24-page pamplet, by Ch. & P. Dadant, Hamilton, Ill. This gives in detail the actions and management adopted in their apiary, toutidins many good and useful hints, and is well orth the price—15c.

Practical Hints to Rec-Keepers, by Chas. F. Muth, Chemnati, Ohio; 32 pages. This pampliet gives Mr. Muth's views on the management of bees, and embraces several of his essays given at Conventions, etc. It will be read with interest by beginners as well as those more advanced in the science of beeculture. Price, 10c.

Kendall's Horse Hook—No book can be more useful to horse owners. It has 35 engravings illustrating positions of sick hoses, and treats all diseases in a plain and comprehensive manner. It has a large number of good recipes, a table of doses, and much other valuable horse information. Paper, 25c.

Chicken Cholera, by A. J. Hill,—A treatise on its cause, symptoms and cure. Price, 25c.

Moore's Universal Assistant contains information on every conceivable subject, as well as receipts for almost everything that could be desired. We doubt if any one could be induced to do without it, after having spent a few hours in looking it through. It contains 480 pages, and 500 engravings. Cloth, \$2.50.

Ropp's Easy Calculator.—These are bandy tables for all kinds of merchandise and interest. It is really a lightning calculator, nicely bound, with slate and nocket for papers. In cloth, \$1.00; Moroco, \$1.50. Chen edition, without slate, 50c.

Sent by mail on receipt of price, by

THOMAS G, NEWMAN, 974 West Madison Street, Chicago, 111.

# EMERSON BINDERS.

Binders for the Weekly Bee Journal, of 1881, cloth and paper, postpaid, 85 cents.

# THE BRITISH BEE JOURNAL.

AND BEE-KEEPER'S ADVISER.

The British Bee Journal is published monthly at \$1.75, and contains the best practical information for the time being, showing what to do, and when and how to do do it. C.N.A.B BOTT, Bee Master, School of Apiculture, Fairlawn, Sonthall, London.

My Annual Catatorue of Vegetable and Flower Seed for 1881, rich in engravings from photographs of the originals, will be sent FREE to all who apply. My old customers need not write for it. I offer one of the largest collections of vegetable seed ever sent on the way Seed House in America, a large portion of which were grown on my six seed farms. Full directions for cultivation on each package. All seed warranted to be both fresh and true to name, so fur, that should it prove otherwise, I will refill the order grafts. The original introducer of the Hubbard Squish, Phinney's Melon, Marblehead Cabbaces, Mexican Corn, and scores of other vegetables. I uvite the partonage of all thot are anxious to have their seed directly from the grower, fresh, true, and of the very lest strain.

est strain. VEGETABLES A SPECIALTY.

Truly, "Time sifts the wheat from the chaff." We lead in Smokers. Our Double-blast Smoker is perfection. See what "the most extensive beekeeper in America" says of our Quinby Smoker:

keeper in America" says of our Quinby Smoker:

Cherry Valley, N. Y., March 22, 1881,

After testing your smokers with others of the best make, I do not hesitate to order two dozen for use in our rapiaries. When we use a Smoker we make a business of it, running it all day and burning hard maple wood, which tests the construction most thoroughly. Those we have been using admit coals into the bellows, which burn the leather. The tube in your Quinby Smoker running further into the tirebox, must prevent this in a great measure.

CAPT. J. E. HETIERINGTON,

If you desire to see a description of the goods we used in securing over 15,000 lbs. of honey from 176 colonies of bees the past poor season, send for our New Hustrated Circular for 1881, which is just rendy.

# The Clover Experiment.

E. E. HASTY.

The kindly notice of myself in No. 7 of the Bee Journal moves me to give its readers an account of what I am trying to do. It is evident to all on a slight examination that the red clover secretes a large percentage of the honey yielded by the entire flora of the Northern States. It is also evident that the most of it goes to waste, because it lies provokingly just a little further down than the honey bee can possibly reach. Bees work at red clover somewhat as boys work at barrels of molasses, getting a little taste while shut out from the grand supply within. In the direction of getting this immense store of choice honey three different lines of effort are being prosecuted. The first, which will be immediate in its results if successful, is that of Messrs. Jones & Benton, of taming and importing the Apis dorsata. For this expensive attempt we owe them a tribute of gratitude, whether they succeed or fail. It seems, however, most likely that this effort will result practically in failure. The dorsata is likely to refuse to live in a hive. That difficulty being surmounted, it is still more likely to perish, even in a hive, during a northern winter. Even if successfully wintered, it is still liable to have demerits that will keep it from being of any practical use to us.

Another line of effort is that of devel-The kindly notice of myself in No. 7

cannot reach the bottom, and every improvement would enable them to get more. But to get all the honey in the present red clover the length of a bee's lighta would have to be nearly doubled —a practical impossibility, most likely. We may suppose that nature has already developed this organ pretty nearly up to the limit its structure admits of.

One other line of effort remains. The corollas of flowers are among those objects in nature that are most easily modtited by human agency. It is probable that we can produce a clover which shall retain the good qualities of the well known farm clover, and differ from it by having a short-tubed flower that

surface of clover tubes, in which they cannot reach the bottom, and every erage is about 42-100 of an inch, and the improvement would enable them to get extreme range about from 39 to 50. Late extreme range about from 39 to 50. Late blooms are somewhat shorter. A vigorous plant, with no bad points about it, having flower tubes considerably shorter than the average, must be obtained and seeds gathered from it. The initial difficulty to be surmounted is this: Nearly all the seedlings from this chosen plant will fail to have short tubes like the present; they will have tubes of average or more than average length. Just a few out of many seedlings will more or less resemble the parent in the desired respect. One of these must be chosen to raise seed from, and the process must be repeated many times until the tendency to long-tubed

ful, is that of Messrs. Jones & Benton, of taming and importing the Lipis dorsata. For this expensive attempt we owe them a tribute of gratitude, whether they succeed or fail. It seems, however, most likely that this effort will result practically in failure. The dorsata tail likely to refuse to live in a hive, and the bees can reach the bottom of. I do tail likely to refuse to live in a hive, and there is a fair prospect so bees with intent to produce a bee with a longer ligula. The right man and a sufficient number of years being given, something could undoubtedly be done in this line. Our bees already reach the bottom of some diminutive clover tubes in the fall of the year; and every improvement would enlarge the number of years being given, something could undoubtedly be done in this line. Our bees already every my novement would enlarge the number of years being given, something could undoubtedly be done in this line. Our bees already every house he says, you find the honey of these loss.

\*\*Liriodendron tulipigra—often called Poplar, in the South.\*\*

\*\*Liriodendron tulipigra—oft

reached. If we can perfect a clover that will have all its tubes as short as 32 we can no doubt improve the honey bee up to that point. I once held a clover head in my hand, the tubes of which I had filled with syrup, and a bee directly under my eye emptied one to the depth of 32-100. I have four different samples of clover that have yielded some heads with tubes as short or shorter than 32. If, however, we can perfect a clover having a tubelength or not over 24, then all our bees, good, bad and indifferent, can take their fill.

1 think that every apiarist, possessed

their fill.

1 think that every apiarist, possessed of any taste or talent in that direction, should give a little time and thought to something in the way of improvement for the common cause—some honey

for the common cause—some honey plant, or some improvement of the bee, or some new improvement of the bee, or some new importation, or some improvement of things used in the apiary, or some new method of apiary work. No one can cultivate all the wide fields, but each can cultivate some little nook or corner. Inside the apiary I choose the native brown bee for my corner. I really don't think he has had a fair chance as yet, and so I incline to let others attend to the imported races. It surely cannot do any harm to the cause to try the effect of a little good breeding on all the races of bees that come to hand.

to hand. Richards, O.

For the American Ree Journal.

# Stingless Bees-Meliponas, Etc.

DR. WM. R. HOWARD.

The Mcliponas, according to Mr. F. Smith, in a paper on Brazilian honey bees, read before the Entomological Society of London, March, 1863. "are insects having wings shorter than the abdomen, the latter being convex and oblong; their mandibles never being denate; while the Triyonas have the wings more ample, and longer than the abdomen, which is short and somewhat triangular, while the mandibles are serrated, denticulate, or sometimes edentate. The Mcliponas are restricted to the new world, while Triyona extends into Africa, India and Australasia." "Gardner, in his travels, gives a list of such species (of Mclipona) as he met in the provinces of Piauhy and Goyaz, where he found them numerous; in every house he says, 'you find the honey of these bose.' where species the teller. The Melinonas, according to Mr. F.

bleaching. The honey is stored in clusters of cups, about the size of pigeons' eggs, at the bottom of the hive and al-ways from the brood cells. The brood cells are hexagonal; they are not deep, and the young ones when ready to burst and the young ones when ready constr from their casement, just fill the whole cavity. The mother bee is lighter in color than the other bee, and elongated at the abdomen to double their length." Smith also states that the female of this genus has the abdomen greatly distended, reminding one of the gravid female of the white ant.

The Meliponas were known to Huber, who experimented with them and made

drawings of their cells.

From the above it will be noticed that the proposition to send queens to the members of the "Stingless Bee As-sociation of America," that should the sociation of America," that should the valuable queens arrive safely, they would certainly be somewhat like the negro's banjo without strings. They could not be introduced in with our common hive bee any more than you could a bumble bee into a hornet's nest, cound a numble bee into a horner shest, and besides, if the bees were sent in full colonies the honey, as Mr. Langstroth suggests, would be so far from the brood nest that they never could reach it; and were this not the case we never could make the management of them withing like proposeful eventions of them. anything like successful or satisfactory; anything like successful or satisfactory; and while right here let me quote an article from the British Bec Journal on the subject of Trigonas, referred to by a correspondent of the Guide: "Although Trigonas cannot sting, an apiarist would be compelled to beat a hasty retreat if he sould attempt to meddle with their nest." (Hives yon see are dispensed with). "For such an offense the little fellows will make a terrible dispensed with). "For such an ottense the little fellows will make a terrible attack on any person, and in an instant the hair and clothes of the attacking party are filled with an offensive squeaking. They cut off his hair." The correspondent further remarks that, "this thing might be taloreted by lady might pondent further remarks that, "this thing might be tolerated by lady apia-rists that possess an extra 'switch' or two, but for those who can hardly af-ford a wig at all, it would be a little exford a wig at all, it would be a fittle expensive unless the price of wigs should decline. Perhaps the importation of this variety of bees might prove a great aid to the barbers, to help them in 'peeling.' As these bees do not use wax, but mud or resin, a new industry might arise in connection with the man-ufacturing of tile, viz: the making of honey cells for the said *Trigonus* to fill honey cells with honey.

Kingston, Tex., March 11, 1881.

# Have we a Reliable Test for Honey?

L. JAMES.

About a year since I purchased a quart of glucose syrup, knowing it to be such, to try it for household use. As we did not like it, the fruit-jar contaming it was set on a shelf in the pantry exposed to a bright light, yet not to the direct rays of the sun. Sometime durdirect rays of the sun. Sometime dur-ing the past winter I had occasion to use ing the past winter I had occasion to use some extracted honey, and going to the pantry to get it I mistook the jar con-taining the syrup for candied honey; but on attempting to get it from the jar, a waxy or taffy-like adhesiveness quite different from that of honey in a like condition excited my surprise at its ad-hesiveness, and to settle the question I was induced to appeal to the sense of taste to assist in deciding the matter. This did not recognize it as honey, and This did not recognize it as honey, and upon inspection the eye readily detected the lack of granulation noticeable in honey, but in its place a waxy or salvelike appearance. When purchased it was of a beautiful color and rather pleasant taste, but now, after having assumed a taffy-like appearance, it has lost its pleasant taste and assumed one quite different with apparently little sweet in it, as if it stood in need of honey or sugar to help it go down.

Having read the proceedings of the Northeastern Convention, on page 70 of the BEE JOURNAL, current volume, I find that body adopted Mr. Root's resolution, that all liquid honey will granulate, candy, or become hard at the approach of cold weather, and that this quality is a sure indication of its purity, etc. Having this sample of corn syrup

hardening process in pure honey. A trial of the mixture of the stuff with honey would alone be the true test as to honey would alone be the true test as to this point. Heretofore I have recognized in the above standard a correct test of purity in honey; but this stuff sold at a high price as the best silver drips, or some other kind of drips, causes me to call in question our reliance on the above test as an infallible one.

I send by express a sample of this syrup for your inspection, and if it is not exposed to sufficient warmth to liquify it, I think you will agree with me that it will require a good eye and an expert to detect the adulteration.

Atlanta, Ill., March 3, 1881.

Atlanta, Ill., March 3, 1881.

The sample received is quite nauseating in smell, but in skillful hands could be manipulated with honey to a degree of perfection well calculated to deceive any but an expert.—ED.]

For the American Bee Journal

## Side-Storing for Surplus Honey.

G. M. DOOLITTLE.

As intimated in the last number of As intimated in the last number of the Bee Journal, I will resume my friendly talk with Mr. Heddon. He says in the Weekly Bee Journal, on page 33, Feb. 2d: "To me, an argument in favor of side-storing is an admission that the shape or construction of the hive of the advocate is faulty." I take it he cannot mean exclusive side-storing for I know of the supplies that the control of the storing for I know of the supplies of the supplies that the same that the sam ing, for I know of no such hive, or any person advocating such a hive. From the expression, "I prefer a top-storing hive exclusively," I understand that he means that "an argument in favor of a hive which admits of both side and top boxes, like Quinhy's, Betsinger's, Doo-little's, etc., is an admission that the shape or construction is faulty." If I am correct, Mr. Heddon uses the "tier-ing up" below in working for low boney. ing-up" plan in working for box honey; i. c., as soon as the first set of boxes are two-thirds full, they are raised up so as to take a second set between those partly tilled and the brood chamber below. I hardly think he would recommend but a single tier of sections on top of each hive, for in such a case a strong colony of bees would not have room enough to work to advantage.

work to arrannage.
Well, I do not know that I can prove
to him that he is making a great mistake in using and advocating "toptake in using and advocating "top-storing exclusively," in any better way than to give my experience, and the causes which led me to believe right contrary to what he does. The year contrary to what he does. The year 1870 was the first really good honey season that we enjoyed after commencing bec-keeping. At that time we used the Langstroth frame and practiced the tiering-up process. At the end of the season we found we had taken from our best colony in the apiary, 140 lbs. of box honey. This I thought a large yield, honey. This I thought a large yield, till I found that Mr. Betsinger had gone considerably ahead of it with side-storing hives. Two poorish seasons followed, during which Mr. B. nearly doubled us in quantity of honey per colony, and in 1873 we made a few side-storing hives to test the matter. Although we found we had over-reached the nearly by mitting for many boxes at though we found we had over-reached the mark by putting too many boxes at the sides, still we could see an advantage in favor of side and top-storing com-bined, for the reason that our bees would build comb much faster at the side than on top, while they would store honey much more rapidly on top than at the sides. Thus we were not slow to learn sides. Thus we were not slow to learn that if we wished to secure a good yield from our bees, we were to raise the sections built full of combs (or nearly so) at the sides, to the top, as fast as full boxes of honey were taken from the top, and placing our empty sections at the sides every time. Thus we worked the sides every time. Thus we worked till 1877, using top and side-storing com-

(or glucose as 1 suppose it to be) before me. I recognize in it an article that if third 286, while our whole lot of side-mixed with honey, would not in all storing hives gave an average of over probability offer any impediment to the 200 lbs. each. This was a clincker in fathird 286, while our whole lot of side-storing hives gave an average of over 200 lbs, each. This was a clincher in fa-vor of side-storing, and, in his lan-guage on page 66 of the Weekly Bee Journal. "I was not prejudiced in its favor because I adopted it," but "I adopted it because I was prejudiced in its favor," and to-day all tiering-up ap-pliances are out of date in our apiary. Candidly, did Mr. Heddon ever, with-out partiality, try the combined plan of side and top-storing? If he has, I can but wonder at his words first quoted in this article. If not, they show his exthis article. If not, they show his expression was a little premature.

I see Mr. Heddon has adopted 8 Langstroth frames as his standard as regards

the number that should be used in a hive. We have adopted 9 Gallup frames, hive. We have adopted 9 Gallup frames, which is about the same as 7 Langstroth frames, and if I was using the Langstroth hive, 7 frames would be all that I would use, for this reason: If we wish to make a success of producing box honey, the frames in the brood apartment must be full of brood (not honey nor empty comb) at the time the honey have a company in not the first that the first harvest commences; if not, the first storing will be done in the space unoc-cupied with brood, instead of the bees going immediately into the boxes, and I have found by experience that if there is room in the brood chamber for the bees to store from 6 to 10 lbs. of the first honey gathered, they are very loth to enter the boxes, thus crowding out the queen with honey, for they will keep crowding her to more or less extent, if such conditions are present, to the end of the harvest. But let them have every of the harvest. But let them have every available cell full of brood, and the first honey gathered will go into the boxes, thus inciting an ambition to store in the thus inciting an ambition to store in the boxes rather than in the brood clamber. I do not wonder that Mr. Porter (see page 73 of the BEE JOUUNAL) failed with "Doolittle's plan," as we see he used 10 Langstroth frames. If 10 Langstroth frames are used (as a rule) the two outside frames will be tilled with honey, and bees will not travel over a sealed frame of honey to go into boxes at the sides while those on top come close to the brood in the center of the hive, at the top of the frames; but let the brood come as close to the side boxes. the brood come as close to the side boxes as it does to those on top, and our experience is they will enter the side boxes first, unless coaxed into the top boxes with full sections of empty comb, as we always do.

In the next Weekly BEE JOURNAL I will give my experience with separators.
Borodino, N. Y., March 29, 1881.

For the American Bee Journal.

## The Discharge of Feces in the Hive.

A. A. BALDWIN.

To the question, "Do bees willingly discharge their feces in the hive?" I say, no! A number of apiarists claim that during the confinement of winter they discharge their feces in a dry state or form. Now if this is so, they must endowed with reason to decide whether they are in a perfectly healthy condition or not. Every apiarist knows that bees when affected with dysentery are very loth to discharge their excrement in the hive, choosing, rather, to leave the hive, even amid the piercing winds of winter. We have many demonstrations of this fact in almost every onstrations of this fact in annost every apiary after this long cold winter. We find some colonies quite badly distended as they come out for their first flight, but on looking into the hive find the combs clean. Now if it was natural for them to discharge their feces in their lifter we also always a clean hive hives we should not have a clean hive or comb after such a long confinement or comb after such a long confinement as they have had in many sections of the country this winter. It is evident that cold and moisture are the two main causes of dysentery among bees; too much dampness, either in their food or in the atmosphere which surrounds them. My experience is that bees will endure a confinement of 5 months or longer and come out in good condition. longer and come out in good condition if all things are favorable. I had my bees in the cellar one winter, 5 months and 8 days, and they came out in good condition and did well the next season. Let us talk up the subject of absorbents. Sherman, N. Y., April 5, 1881.

## North-Eastern Wisconsin.

At the North-Eastern Wisconsin Bee-Keepers' Association, held at Osh-kosh, the following topics were dis-cussed:

### Different Races of Bees.

Mr. Winslow, I decidedly prefer Ital-

Mr. Winslow. I decidedly prefer Italian bees, the purer the better.
Mr. Potter. I prefer Italian bees, decidedly: they protect themselves much better. I have 180 colonies and got 1,500 lbs. surplus.
G. S. Church. I have only black bees;

Thave kept them for 20 years.

Geo. T. Sanford. I found less difficulty in wintering black bees.

M. A. Gill. I have no choice as to race,

but consider as superior those of any race that are vigorous and have ragged wings, which denote hardiness and longevity and that bear their loads to

the hive entrance without lagging.
Conrad Dippel. I certainly prefer
Italian bees on account of gentleness.
C. Grimm. I keep black, Italian and

hybrid bees.
Jacob Childs. My 20 years experience gives preference to Italian bees. On a scale of 7 they mark 7 on swarming; 6 for docility and gentleness, and 6 for becaute. beauty

John Dickinson. I have had no experience with black bees. Hybrids begin work more readily in sections, the leather-colored Italians coming next. As to industry and general working qualities, Italians have given proof of their superiority. Hybrids come out stronger in the spring and get through a cold winter better, but Italian bees build up more rapidly.

## Best Method of Wintering Bees.

John Hodgson. I tried different ways each year for 8 years and decided the cellar the best. It should be built on a side hill and kept at a temperature of a side hill and kept at a temperature of 35 with a pipe to carry off foul air.

Alr. Potter. I favor the cellar. I have tried chaff hives and have lost all.

I have 90 colonies in a room 14x22; have no trouble with mice; put chaff over the hives

the hives.
Fred Badger. I have wintered bees in Iowa, never here till now. My bees are now standing out and in good condition. I use chaff boxes 6 inches deep over the frames.
Mr. Potter. Bees will stand temper-

Mr. Potter. Bees will stand temperature at 45 and live.
Fred Brooks. My brother found a bee-tree a week ago and found the bees very lively.

very lively.

Mr. Winslow. I keep my bees entirely on summer stands packed in wheat chaff and burlaps. I have had unsatisfactory experience with cellars.

L. Fatzinger. My bees invariably succeed best in the cellar.

D. Abott. After various experiences I prefer the cellar, with a temperature of 35 to 40, with ventilation from without and no

out and up.
Jacob Childs. I nevertried anything except out-door wintering packed in chaff—out, wheat and buckwheat—with equal success.

Christopher Grimm. I favor cellar wintering.

Conrad Dippel. I favor chaff hives

Conrad Dippel. I favor chaff hives on summer stands.
Geo. T. Sanford. I favor chaff hives.
M. A. Gill. I maintain that north of parallel 40, a cellar if perfectly pure and dry, and all light excluded, is preferable.
John Dickinson. I winter ¾ in the cellar and ½ out-doors packed in pine sawdust or chaff. Those out-doors are placed with backs to a terracel wall sawdust or chaff. Those out-doors are placed with backs to a terraced wall and covered with factory cloth and straw and old hay. In this way they winter rather better than in the cellar. C. J. Hennings. The best method of wintering bees is to bury them.

## Is Upward Ventilation Necessary in Winter?

Mr. Potter. I uee upward ventilation. C. J. Hennings. Give them ventila-tion at one end on the lower part and at

the other end upwards.

M. A. Gill. In cellars upward ventilation more than a quilt would give is needless, but on summer stands direct upward ventilation is necessary.

Geo. T. Santora.
Conrad Dippel. Upward ventuation is needed, and as much as 4 inches of chaff will allow.
C. Grimm. It is necessary in cellars Geo. T. Sanford. Answers yes. Conrad Dippel. Upward ventilation

chaff will allow.

C. Grimm. It is necessary in cellars but not out-doors.

Jacob Childs. I consider upward ventilation quite necessary, but let it be through 10 inches of chaff, and burlap between the bees and chaff.

L. Fatzinger. I think it necessary if done without a draught through the hive

Mr. Winslow. In chaff, only such upward ventilation as will go through

ward ventuation as will go through light chaff and burlap.

John Dickinson. I have tried it with and without ventilation and find no particular difference.

# Amount of Food Bees Consume in Winter.

It was generally conceded that it depended all on the length and severity of the winters, place of keeping, etc. No one seemed to have weighed their bives but, fall and provide the control of the contr hives both fall and spring to ascertain with exactness. Some thought 25 lbs. was none too much, while others thought they had wintered swarms on as low as 10 or 15 fbs.

## Mistakes of and Hints to Beginners.

The sentiments expressed are about all one way—go slow and do not increase too rapidly. Some of the individual ex-pressions were as follows:

mr. Potter. Beginners increase too much. They should keep their bees strong; they should never keep more than 5 colonies the first year and 10 the second.

Mr. Gill. Beginners make mistakes in getting too many bees before acquiring thorough knowledge of them, and too rapid increase leads to disaster. They should commence with 2 or 3 col-

They should commence with 2 or 3 colonies—never more—adopt some standard hive and study the bee periodicals.

Jacob Childs. If you would succeed go to some practical and successful beekeeper and learn the trade.

Conrad Dippel. The principal mistake is in dividing too often or letting them swarm as often as they please. Beginners should never depend on bees and honey alone for a living. and honey alone for a living.

C. Grimm. Do not invest much at the beginning.

## Wintering on Grape Sugar.

Wintering on Grape Sugar.

Mr. Hodgson. I fed 5 colonies on grape sugar last winter and lost 4 of them. Will never try it again.

Conrad Dippel. I do not feed, touch nor handle it; I am entirely averse to it.

C. J. Hennings. I never had success with grape sugar.

John Dickinson. I tried it thoroughly with bees in the cellar, but had to take it out by Christmas. One colony of bees was dead and the rest were in a bad condition. I dread grape sugar and will let it alone. will let it alone.

# Best Method of Swarming for Wisconsin.

Mr. Potter. This is a fine point. The past season artificial swarming would ruin colonies and to rely on natural swarming would give no increase. If you rely on natural swarming you must have your colonies very strong early so that they will swarm by the 14th of

June. I recommend natural swarming.

Mr. Church. I do not like to let them
increase at all, but practice both natural
and artificial swarming. I move natural swarms as soon as hived to the place

where they are to stand.

Fred Badger. I use a mullen stalk tied on a pole, and in every instance the swarms would cluster upon it.

the swarms would cluster upon it.

Mr. Winslow gave an instance where a bee-keeper he knows uses a long pole with a wad on the end covered with black alpaca, resembling the color of bees, and catches swarms every time.

Mr. Potter. I sometimes clip the queen's wings and when she comes out I catch her. When the swarm is out I replace the old his with a representation.

I catch her. When the swarm is out I replace the old hive with a new one and turn in the queen loose, when the swarm will return to the new hive.

Mr. Haight. I do not approve of clipping queen's wings and do not practice it any more. Could not work it with a large number of colonies.

Conrad Dippel. In Wisconsin I find dividing the best and most easy method of increasing the number of swarms.

C. Grimm. I favor natural swarming, but if rapid increase is desired, dividing should be practiced.

Mr. Gill. For the specialist natural swarming is preferable, but for those engaged in joint business—farming and lookening dividing in the west do bee-keeping-dividing is the most de-

L. Fatzinger. The best way is to let them swarm once, then cut out the queen cells and introduce a laying

queen.
John Dickinson. I could not stand natural swarming in an apiary of 100 colonies or more. Too much trouble. I believe that bees do work just as well when properly divided as when allowed to swarm naturally.
C. J. Hennings. I believe it best to let them swarm once, in Wisconsin.
Jacob Childs. Either way is good, according to circumstances, which must be determined by judgment.

be determined by judgment.

Geo. T. Sanford. I prefer natural Geo. T. Sanford. swarming.

## When to Divide Colonies.

Mr. Potter. If bees are strong and old combs plenty divide as soon as the clover yields; if they have only honey, divide in May. Mr. Winslow.

I find second crop of

white clover valuable.

Mr. Green. I divide as soon as bees

are strong enough. I get most of my honey in the fall.

Mr. Gibbons. I divided both ways and found those divided after clover

season did the best.

Conrad Dippel. I consider the best time after elover season and before lin-

den blossoms.
C Grimm. If the colonies are strong C. Grimm. If the eolonies are strong divide before, if weak, after clover sea-

son. Geo. T. Sanford. Before, if strong

enough.

Mr. Gill. 1 would advise dividing only in exceptional cases before clover

M. Mahin writes: If increase of stock is desired without regard to quantity of surplus honey, divide at the beginning of the white clover season; if a larger amount of honey is desired with a moderate increase, divide after clover season. If the largest amount of honey possible is desired and no increase, don't divide at all.

# Does it Pay to Melt Old Combs and Use Foundation?

Mr. Potter. Not if the comb is whole and straight.

Mr. Green. I had the best success

with new foundation.

Contad Dippel. Comb foundation is indispensable. I give it to new and old colonies after dividing.

Mr. Gill. Not necessary with straight

worker combs.

L. Fatzinger. If clean, straight comb save it; otherwise melt.

John Dickinson. It decidedly pays to do it with present price of wax and foundation, even without a machine.

C. J. Hennings. It does pay.
Mr. Sanford. 1 think it does.
Mr. Grimm. It does, if convery old and part drone cells.
R. A. Morgan says it does. and combs are

A. Morgan says it does, and gives practical tests in support of it.

# Division Boards and Surplus Honey.

All agree that they are useful early in the season, and may be used in the upper story to induce bees to work more readily, and in the lower to increase breeding by keeping the bees warmer.

## Is the Basswood in this State Killed?

Few of those present had any know-ledge on the subject, and the letters received varied somewhat, some thinking not and others deploring the rapid de-struction of basswood. Several comstruction of basswood. Several con-munications urged bee-keepers to set out linden trees and have them prop-erly guarded and fenced in.

The North Eastern Bee-Keepers' Convention all through has been somewhat informal, although considerable interest was manifested by the few in atten-

est was manifested by the few in attendance. Tuesday afternoon the following officers were elected:

President, Geo. S. Church, Neenah.;
Secretary and Treasurer. Mrs. Frances
Dunham, Depere; Vice-Presidents, L.
H. Pammel, LaCrosse; John Hodgson,
Pewaukee; C. H. Green, Berlin; A.
Potter, Eureka, and H. P. Sayles, Hartford

A resolution was passed to hold the next meeting in Berlin on the second Tuesday and Wednesday in October, but at the evening session this resolution was reconsidered and the place fixed for Pewaukee, at the same time mentioned.

Read before the N. E. Convention.

# Wintering Bees Successfully.

L. M. WAINWRIGHT.

Heat and electricity are the staple, vital forces of life in animal organization. Combine all the other favorable circumstances that a smiling Controller of the universe could bring about, in absence of the great forces, and atl is wrapped in the chilly sable mantle of an eternal sleep. Could it be that na-ture should be clothed in her mantle of grandeur, watered by the silvery sprays of the welcome clouds, with the rain-bow's glories seen through the misty vapor, and the sun alternately shining in his glory, yet with the earth's nor-mat condition of heat and electricity absent, the cold, icy arms of death would chill all the pulsations of life, and cause everything to sleep quietly in the stilly shades of universal night.

Before late autumn's and early winter's chilly winds scatter the hoary frosts, all colonies should be prepared for winter under the genial rays of an Oxtober's grown

October's sun.

## How to Prepare for Winter.

Remove the top story of the hive, take off all surptus honey boxes and remove the outside combs from the brood chamber, leaving in the center of the hive only enough well-filled combs to carry the bees safely through until spring. Place the lids on the brood chambers, and they are ready to wheel into winter quarters as soon as the proper time comes, which varies with latitude; but in Central Illinois, as a rule, about the middle of November.

## Winter Repository.

It may consist of a dry underground cellar, a cave in a hillside, or a frostproof building on top of the ground; but as the style of the repository is no part of the discussion, we leave this part of the subject for others to decide.

## Cleansing the Repository.

If the building is infected with mice, trap them all a month or so in advance of putting up the bees, and a few days before the bees are housed burn a suitable amount of sulphur in the room to destroy all accumulations of fungi, then with a suitable brush wash the walls with a weak solution of carbolic acid and water, after which leave the house If clean, straight open until all is sweet and pure.

# Storing in Winter Quarters.

Select a nice cool day or evening about the middle of November, soon after the bees have had a purifying flight. Close up the entrances of the hives, and place 1 or 2—or as many as hives, and place 1 or 2—or as many as as you are prepared to wheel—on a spring wheelbarrow, if you have it, if not, a common one will do, running it on a smooth track. Wheel directly into the repository, and stack your hives one upon another as high as you can lift them, atways being careful as you stack them to raise each hid ½ inch above the hive all around by slipping under the hive all around, by slipping under the lid a suitable number of ½ inch pieces prepared for the purpose. Avoid placing the hives against the walls of the building, as this might produce a concussion among the bees from an outside jar of the building.

## Winter Management.

After the bees are properly adjusted in the house for the winter, 3 things are to be considered. First: A proper temperature of the atmosphere. Second: Plenty of fresh air. Third: A humid condition of the atmosphere.

(1.) The murcury should show a higher or lower temperature in proporhigher of lower temperature in proportion to the strength of the colonies housed. If the colonies are very strong,  $40^{\circ}$  Fahr, is about right. Medium colonies, from  $45^{\circ}$  to  $50^{\circ}$ . But if very weak, or nuclei with queens, about  $50^{\circ}$  is necessary to keep the bees in a good, healthy condition. Colonies should be

graded according to strength, and placed in repositorics adapted to their wants

Sometimes when bees begin to leave abyss before them, "never, never" to return to their once happy homes, we are liable to attribute the whole excitement to too high a temperature, while the facts are that the atmosphere is too

ment to too high a temperature, while the facts are that the atmosphere is too dry, and the bees thirsty after a long conlinement.

(2.) Bees, like animals of a higher organism that live and bask in the great ocean and sea of atmosphere—which alike in all places enshroud the globe, imparting life, vigor and health—should have plenty of fresh air. True, bees can live in an atmosphere so foul, and breathed over and over so frequently that a human being would soon die in it. But this is no argument in favor of wintering bees in a room filled with inpure air. Air should be admitted through a subterranean air duct. If 15 or 20 rods long, and passing through a 6-inch tile, the air will enter the room at 40-, while the mercury stands at zero in the open air.

(3.) A humidcondition of the atmosphere may be kept up by placing vessels of water in the room; but bees do not particularly want water before sometime in January, especially if the honey is thin.

Should very warm weather occur at

honey is thin.

Should very warm weather occur at any time in the winter, the mercury rising to 60° day and night in the open air, no one should take fright and rush their bees out doors, probably to be frozen in a very short time. In propor-tion as the thermometer in the room rises above a proper temperature, in-crease the surface of the water pools in the house, and throw all the doors open at nights, and the result will be the same as produced in a damp atmosphere in the spring, with a temperature of 60°.

Combs will not grow moldy inside of 4 months in a damp atmosphere, if in a well ventilated hive filled with a good colony of bees, and the house properly warmed. Combs will grow moldy when warned. Combs will grow moldy when a hive has no upward ventilation and the room is cold, but more especially if the swarm is small, even if there is no water in the room. It is a cold atmosphere that kills bees and molds combs in a house. The vapor exhaled from the bees not only settles on the outside of the combs, but after a time finds its way into the cells and lodges in small drops against the septum of the cells and creates a heavy fungi in a short time. time.

# How Long Should Bees be Housed?

As a rule they should be kept in until they can gather some pollen from the soft maple and willows. It is not the length of time that bees are confined that stupefies and kills them, but the unfavorable circumstances under which they are confined. Where they are kept warm and in a room with a moist atmosphere (but otherwise dry), and have plenty of fresh air, they never eat more than the system requires to supply the loss that is continually going on in

the loss that is continually going on in animal life; and when brought out after 4 months' confinement, they are as perfect as when winter overtook them. When they are old before housing, they will die in the spring before young bees in sufficient numbers can take their place to sustain the "old homestead." We call this spring dwindling. Other unfavorable causes will produce Other unfavorable causes will produce

like results.

I will not argue the question of repository wintering, as it is vastly better in a cold climate. As the "Sunny South" always enjoys the blushing smiles and geniel rays of a warm sun, the bees will care for themselves in such adimpata. Not so in the North where a climate. Not so in the North, where the mercury falls to 25° or 30° below zero, and remains down so long that they cannot take wing for 6 or 8 weeks. They will generally perish and become unhealthy if on their summer stands. unhealthy it on their summer stands. Chaff packing in ordinary winters will keep up a very good temperature outdoors; but alas! when it sinks 30° below zero, and the winds are sweeping over hill and dale like a mighty tornado. winter's icy breath severs the tender cord, and life gives place to the still reign of death.

Noblesville, Ind.

## THOMAS C. NEWMAN.

EDITOR AND PROPRIETOR,

CHICAGO, H.L., APRIL 13, 1881.

In Bohemia, Austria, the Society has changed its name to" The Austrian Society of Bee Friends," and has elected Herr R. Mayerhoeffer its President, who in a recent letter says: "I am surprised that you can publish the BEE JOURNAL as a Weekly-such a thing is only possible in America. I wish you the best of success."

The Indiana Farmer says that the annual report of the Bureau of Statistics, just out, places the number of colonies of bees in the State at 146,327, and the number of lbs. of honey taken, 1,197,627, or 8.18 lbs. per colony. This report is for the honey crop of 1879, which was a very poor season, the estimated yield being only half a crop. Lawrence county reports the largest number of colonies, 7,168. Allen county next, with 4,114. Crawford county the least, only 142 being reported. In production Lake county stands at the head with 59,984 lbs.

A disgusting discovery was recently made near Birmingham, Enggland. The Mark Lane Express of March 7, says :

"The Inspector found in the 'manu-letory' the steam machinery in operafactory 'the steam machinery in opera-tion, and about 1.300 lbs. of diseased stages, from the 'raw material' to the 'finished' potted meat, sausages, saveloys, 'savory ducks,' German polonies, etc. There were nearly 200 lbs. of sauloys, 'savor, sages recently made, and colored with red ochre to give them a fresh appearance; 2 diseased sheep, 200 lbs, diseased horseflesh, and cans of potted meat, being mostly diseased horseflesh.".

# Uniting Colonies in Early Spring.

Will you please to tell me, through the BEE JOURNAL, how to put 2 colonies of bees together and manage them so they will not light?

Mrs. H. Thompson.

Vermontville, Mich.

Cook's Manual, page 253, recommends spraying and smoking for successfully uniting in summer and fall; but in quite early spring there is some danger of chilling brood, if the operation is performed by unskilled hands. We think the following will be the best plan for early weather: Remove the queen from one colony and put the frames with bees and brood at one side, putting in a divider made by tacking wire-cloth on one side of a brood frame, with the ends extending to reach full length of the hive; now bring the brood, queen and bees from the other hive and place in this one, close the entrance on the bees and queen, put in for 24 hours, slant a board in front, remove the hive vacated. the next night, remove the obstruction which had been better forgotten. from the entrance, leaving the slanting board in front, which will cause the bees to mark their home anew. On the third day remove the dividing-frame should occupy the old stand, from which several days.

## Conventions, and their Mission.

I have been thinking of the real solid risits and enthusiastic discussions we have at our Conventions. In these dis-cussions we get not only the last and hest thoughts of the participants, but inspired thoughts—truths told with masks off. Prof. Cook says enthusiasm is the main source of successful honeyproducing, and much more is it the suc-cess of a bee-keepers' Convention. But our Conventions are universally marred by long and tedious essays. Just as the meeting has reached a degree of warmth that is inspiring, the Secretary hauls out a long essay (may be a "prize es-say"), and reads, and reads, till the glow of the members is charred to coal. its close every attendant feels tired and like a man in a wet blanket. D. sighs, M. draws a long breath, B. yawns, and then all hitch in their seats, and a siekly silence comes over the scene. But soon the next topic is taken up, and a new enthusiasm kindled, which is destined to the same fate. It seems to me that the offering of "prizes" for these essays to promote and encourage (on-pertions to promote and encourage Conventions, is like paying a premium on murder to promote morality. Is there any argument in their favor that is not answered by saying, "Send them to the JOURNAL as correspondence?"

At our meetings we are never at a loss for interesting topics, but for the time to discuss all that we can feel are of importance to us. Those who are in atportance to us. Those who are in attendance have borne the expenses, and have a right to the time over the essay ist. A short letter of greeting, and now-and-then a topic suggested by an absent member, would not be so bad. Do you not know that what I have slated above is true, from your experience

at Conventions?

Topics should be suggested and pubsome days before the meeting. and each member or proposed attendant should prepare himself to speak on the to speak on the subject by revolving it over in his mind. Of course, we are not orators; but neither are we essayists. While some of us are not gifted at theorizing and drawing deductions, all can tell their experience in some shape, and what is of more value? Experience is the of more value? Experience foundation of the whole fabric.

District Conventions are what we Good reporters are next in order. We want a report that is condensed in words, but not in thought. A man to fill that office must possess a knowledge of the topic under discussion, and a su-

perior power of handling words.

The bee-keepers of our Congressional District, embracing this southwest corner of Michigan, are now taking steps for an organization, and although I am so busy that I cannot help it along as much as I would like to, yet I will do all I can, and hope we may soon be organized permanently. I believe I prophesied such local Conventions some years ago.

JAMES HEDDON.
Dowagiac, Mich., March 23, 1881.

We must take occasion to thank Mr. Heddon for broaching this subject in his terse, happy manner. It must have occurred to every reader of the BEE JOURNAL, as it has frequently appeared to those in attendance at the Copyentions, that some of the essays were long and prosy, and frequently two or more upon the same subject; while the essayists themselves must have felt the necessity for prolixity, in order to meet supposed arguments which might be opposed against theories advanced. It frequently happens that much valuable time is occupied in this way, that would have been saved had the writer been and the work is done. In 24 hours, or present, and many records perpetuated

We should not forget, however, that many discoveries are being made, many exceptions to acknowledged rules frequently occurring, and apparent contraand the board from the front. No hive dictions of theories arising. These should be brought before the Convenshould be brought before the Convention for discussion. Some one present can probably explain a seeming mystery violation of this act shall for each ofthe queen and bees were removed, for tion for discussion. Some one present

their experience.

Mr. Heddon is correct in his estimate of the value of good district Conven-They harmonize what would otherwise he competing interests; they foster a fraternal feeling; they encourage an emulative spirit of superiority. and elevate the nobler instincts of humanity.

The Secretary might be chosen with especial reference to his apicultural knowledge and reportorial qualifications. Promptness in making out his report, if intended for publication, is quite as essential as promptness in attending to any other business entrusted to him. The reports of a conventional body lose much of their interest to the members in attendance if not published promptly, and an editor feels much re-Inctance in giving his readers a stale report, when, perhaps, his correspondence files are crowded with communications of recent date.

By all means, organize district societies and call Conventions, then let every bee-keeper within their circuit make an effort to altend. If one bee-keeper is more successful than another, he is under a moral obligation to attend his Convention and instruct his co-workers; if he is less successful than they, he is under a pecuniary obligation to himself to attend and be educated. Leave all personal differences to be settled outside the Convention, and all work with a zeal to make it a pleasant, successful and profitable gathering.

# Wisconsin Law against Adulteration.

Mr. F. Wilcox has sent us the following questions:

I append hereto a copy of our law in relation to the adulteration of food. What do you think of it; can it be en-

Bees that are being wintered on the summer stands are in very bad condition (mostly dead), unless well protected. Those in cellars are in good condition, but need a flight soon. The weather is but need a flight soon. The weather is very cold yet, and little or no bare ground. We must wait another month before we can accurately tell how bees have wintered.
Mauston, Wis., April 2, 1881.

# CHAPTER 40.

An AcT in relation to the adulteration

of food.

The people of the State of Wisconsin, represented in Senate and Assembly,

do enact as follows:
Section 1. Every person, company or
corporation who shall manufacture, sell
or offer for sale any article in imitation of butter which has been manufactured wholly or in part from tallow, shall mark each firkin, tub, package or parcel, on top of same, in letters of not less than one-half inch in length, and breadth in proportion, and in such manner that it may be plainly seen, the word "oleomar-garine." If made wholly or partially from lard, each firkin, tub, parcel or package shall be marked "butterine" in

large letters, as above required.
Sec. 2. Every person, company or corporation who shall sell, or offer for sale, honey, or any imitation of honey which noney, or any finitation of noney when is adulterated with glucose, or any other substance, shall mark the package or parcel with the words "adulterated honey," as required by section one of this act.

Sec. 3. Any person, company or corporation that manufactures or offers for sale cheese that has been made in part of oleomargarine, or where anti-huff or any other substance has been used to adulterate the same, shall mark each cheese as required by section one of this act, with the name of the article or ar-

in a few words; others may profit by fense be punished by imprisonment in the county jail, not less than ten days nor more than six months, or by a fine of not less than ten dollars nor more than one hundred dollars, or both, in

the discretion of the court. Sec. 5. One-half of all fir tines imposed by the enforcement of this act shall be paid to the person who informs against and prosecutes such offender to conviction.

Sec. 6. All acts or parts of acts conflicting with the provisions of this act are hereby repealed.
Sec. 7. This act shall take effect and

be in force from and after its passage and publication.

Approved March 3, 1881.

Another dead-letter, we fear. It is not made the especial duty of any officer to prosecute offenders, nor is the tribunal designated which shall have cognizance in such cases. Again, there is a fatal omission of the nature of testimony which shall be required to secure conviction, and statutory as well as common law pre-supposes every offender to be innocent until proven guilty. As in Kentucky, the real difficulty will be to prove the existence of the fraud to the satisfaction of the jury.

But we are glad to see that the law has passed, even though it should prove inoperative. It is a strong evidence that the people are awakening from their lethargy and demanding reform. The abuses are so great that it seems difficult to check them, but the next legislature can amend the law to make it effective. if the honest producers and consumers combine in requiring it.

## The National Convention.

We have received for publication the following letter from the President of the North American Bee-Keepers' Society, in reply to Prof. Cook's open letter published in the Weekly BEE JOUR-NAL of March 23d, page 92:

Smith's Grove, Ky., April I, 1881. Prof. A. J. Cook: Dear Sir: I have read with much interest your sugges-tions to the Executive Committee. through me, to fix the time of holding the North American Bee-Keepers' Convention, at Lexington, Ky., on Wednesday and Thursday, Aug. 24 and 25—the week after the American Association for the Advancement of Science meets

Cincinnati, O. It seems to me that would be a favorable time for holding the Convention, but our Association is so extensive, embracing, as it does, the whole of North America, it is difficult to decide the best time for holding the Convention. I thank you, sir, for the interest you manifest in the Convention, and will be glad to receive suggestions from other Vice Presidents and bee-keepers generally who feel an interest in the matter. The reduction of railroad rates will have much to do with the number attending the meeting. In October the Louisville and Cincinnati Expositions arrange for reduced rates, and members passing through could get the benefit of the reduction. But, as you state, we might be able to get the commutation of railroad fares to extend to the meeting at Lexington. We hope to have a very large attendance, and the most interesting meeting that has ever been held by the bee-keepers of North America.

As soon as the Executive Committee can determine on the time, it will be can determine on the time, it will be made known through the bee papers. Meantime, I hope to hear by letters or postal cards from the interested bee-keepers, expressing their preferences. with reasons, for the time of holding the next Convention,

Very truly yours, N. P. ALLEN.

The Semi-Annual meeting of the Champlain Valley Bee-Keepers' Association will be held at Bristol, Addison Co., Vt., May 19, 1881.

T. BROOKINS, Sec.

# SELECTIONS FROM

Halian Bees Superior.—Bees are doing well here this season. Swarming commenced March 30; they are storing honey in boxes, which are half full now. I had 40 colonies last fall and lost none in the story of the stor in the winter; and none were even queenless. They are all Italian bees. Native bees are a failure as compared with the Italians, as I have demonstra-

ted during the past 4 years.
B. C. YATES.
Weatherford, Tex., April 3, 1881.

Box Hives no better than Others. - My bees are all dead; they died of cholera. They have died at a very fair rate reliable box hive, so the "I o's " have to take a back seat. told you so's as the scientific apiarist has not killed his bees this time. W. P. EVRITT. Davis, Mich., April 5, 1881.

Little Discouraged. - Nine-tenths of all the bees in this part of Ohio are dead; in fact there are hardly any left. Of those remaining, the greater portion are in box hives, unprotected. What is Of those remaining the greafer portion are in box hives, unprotected. What is the eause of that singularity? I had mine packed according to Prof. Cook's theory, and all but a few perished, and they are very weak. All left plenty of honey in the hive, and all had the dysentery. I have about 400 frames of comb, the greater part of which have some honey nicely capped, and I want to save them for future use. I. How to save them for future use. 1. How can I protect them from the moth? 2. Should I extract the honey from them?

3. Is there any advantage in feeding weak colonies when there is plenty of honey in the hive?

4. Why do not some of the more successful bee-keepers give to the public, through the Bee Jour-Nal, their mode of wintering? I have reason to feel a little discouraged. The

JOURNAL is a welcome visitor. L. Z. Lantz. West Liberty, O., April 4, 1881.

[We presume, when a final balancesheet is struck, you will find the boxhive bees have fared no better, if as well as those in approved hives.

I. By placing them in tight hives, elosing the entrances tightly, spreading papers on the top projecting beyond the hives, fitting the covers on nicely, then putting them in a cool room.

2. Yes; we prefer giving them empty. one or two at a time.

3. No; it is injurious. If you wish to stimulate breeding, give each day a little honey and water, in equal parts, at the entrance. A Shuck feeder is very good for this purpose.

4. Nearly every number of the Jour-NAL contains letters from successful bee-keepers, giving their methods of wintering.—ED.]

A Confinement of 148 Days.—This has been a most disastrous winter for bees, so far, and the end is not yet. The weather to-day is more like December than spring. Nine-tenths of cember than spring. Nine-tenths of the bees that were not well protected have died, and the other tenth will probably die if they are not fed. Bees that are well cared for have fared bet-I have 3 colonies in the cellar and one on their summer stand, packed in chaff. They had a flight on March 26, after a confinement of 148 days. We had no surplus honey nor increase last year but I look for an abundant yield this season. I am located 147 miles this season. I am located 14 miles south of a grove of linden of from 1,500 diameter, will my bees go there for honey? They are blacks and hybrids. honey? They are blacks and hybrids. I want to Italianize in the spring. I find that nearly all of my neighbor beekeepers that do not take a bee paper are the heaviest losers in bees. Success to the Weekly BEE JOURNAL.

L. W. WBEN.

West Branch, Iowa, April 4, 1881.

making slow progress. Plums and peaches are nearly a month later in blooming than usual, and so far have been but little benefit to the bees. weather still refuses to let loose, despite the prophets, but hope points just ahead to genial spring time. The Weekly is a success. "Onward" be its motto.

S. D. McLean.

Culleoka, Tenn., April 1, 1881.

Cold in Kentucky.—This is a very cold ay for April 1st. Snow has been fallday for April 1st. Snow has been fall-ing for 48 hours, but melting as it fell. The ground is now frozen and the wind is blowing strong from the north. Bees are in bad condition except where well protected. Mine are all right yet with protected. Mine are all right yet with their chaff cushions, and have plenty of stores. I lost but I colony out of 40, and that was a late artificial swarm. I hope for a good honey yield and a prosperous season. Fruit blossoms are ready to open the first warm days, and the white open the first warm uaye, elover is very promising.

Smith's Grove, Ky., April 1, 1881.

Loss of Bees.—This has been a very hard winter on bees in this locality. Mine were confined to their hives from October 16 fill March 13. The weather Mine were connued to their mives tron. October 16 till March 13. The weather is still cold and winter holds on. I think about 3 will be lost by April 15.

GEO. GARLICK.

Warsaw, Ont., April 1, 1881.

Bees in Fair Condition.-Bees in this vicinity that were wintered out-of-doors are under snow banks some 8 feet deep, and still the snow is coming. banks cover the tops of the fences in many places and we can drive over a 4board fence without taking down the fence. My bees have the dysentery, but I cave them a flight on March 18. I I gave them a flight on March 18. left 50 colonies out all night as it was a fair day, but the morning of the 19th soon turned out to be one of the worst blizzards we have had this winter. bilizards we have had this winter. I succeeded in putting my bees all back in the cellar by calling up the neighbors to help; it became a perfect gale before we got them all in. They now seem to be ready for another map. In my bee yard the snow is from 3 to 8 ft. deep, a splendid time to trim truit trees deep, a spienmi com as we need no ladder.

D. G. Webster.

Parks Corners, Ill., April 4, 1881.

Safely Wintered.—My bees are in excellent condition this spring, considerthrough. Last fall I had 8 colonies, all hybrids. I prepared 5 for winter by reducing to 3 and 4 frames each, with division boards placed on each side of the brood nest; each hive having about 10 or 12 lbs. of honey; size of frame 11<sup>1</sup><sub>4</sub>x 11<sup>1</sup><sub>2</sub>, they are now in good condition with had in 2 story hives I prepared for win-ter by taking off the top sections and leaving the bottom section with the 8 frames, full of honey (about 35 lbs.) in each hive. One warm day about the middle of January, when other colonies were lively and flying, they did not make any show. Upon examination I found every bee dead and not a drop of honey in either of the 3 hives. I was rather surprised at this loss, and examined one of them and found that they had plenty of stores and very few dead bees; all wintered on their summer stands. I do not use chaff-packing or lime (the lime is new to me) as I can have good results without them, and it is a big job to prepare a number of col-onies for winter. With the hive properly adjusted with division boards inside, a space of 6 or 8 inches from the divia space of sion board to end of hive, a thick cotton quilt on top of frames to absorb moisture and a few thicknesses of paper on the quilt to prevent the escape of heat, they are in an excellent condi-tion to stand a zero freeze, as my 5 colonies have proven to be at this time. The 3 that starved had more space and honey than they required, and consumed honey to keep warm on the same

Spring Prospects.—We are having a late and backward spring. Bees are housed up nearly all the time, and are very simple and natural; the bees have many, but when properly examined is very simple and natural; the bees have died from old age more than anything else, as very few bees were reared last fall. During the months of August. September and October we had very warm, dry weather and no honey in the few flowers that did bloom, and when honey ceases coming into the hive the noney ceases coming into the live the queen almost stops depositing eggs, even when they have plenty of stores for winter, and the majority of the bees being old, they were in poor condition to pull through a long, cold winter such as we have had. As all old animals require more nourishment to keep up a given temperatura them young animals. given temperature than young animals under the same circumstances, and very few young bees being reared during se-vere cold weather to keep up the colony the natural consequence is death, with plenty of stores around them. These are my ideas on the great loss of bees this winter. Shall be very glad to hear from others on the same subject, as a change of ideas brings out the truth.

J. S. DUNCAN. Browning, Mo., April 4, 1881.

The Dying and the Dead.—About <sup>1</sup><sub>3</sub> of all the bees in this county last fall have now gone "where the woodbine twineth," and this month with next will certainly bring this up to <sup>1</sup>/<sub>5</sub>. I have lost but one in 127 as yet, but am fearful that by the first of June 1 shall tell a different story as to losses for the a different story as to losses for the whole season. N. F. CASE. whole season. N. F. C. Glensdale, N. Y., April 4, 1881.

Loss of Bees in Northern Michigan.-I have made some inquiries and have so far to report the loss of 604 out of 933 colonies in this section of the country. This will not fully cover the loss; the present cold weather will reduce the 600 about as much as the "Noble Six Hundred" we read of.
L. C. Whiting.

East Saginaw, Mich., April 5, 1881.

Bees In Middle Tennessee. Weekly Bee Journal. It has been raining and snowing all day here, in middle Tennessee. Yesterday was a beautiful, pleasant, spring-like day. Peaches and plums are in bloom. Bees were working like beavers; to-day all are frozen up. If we could have 10 are frozen up. If we could have 10 warm days our bees would be safe. I have rye-meal, honey and sugar. I put into winter quarters 8 colonies in Langstroth hives; lost only one, which was short of stores and came out in Febru-ary and ran off. I wintered on the summer stands, sheltered and packed down with cotton seeds and mats; I packed underneath the hives with sawdust. There is only one requisite here in wintering bees and that is to have plenty of stores and to keep them dry. This has stores and to keep them dry. This has been a remarkably hard winter; many of the late swarms in box and gum hives have starved. This is a very tryof the late swarms hives have starved. This is a very uy-later to have apparent to have up rom Indiana here trying to buy in native bees. I. A. Burrow, M. D. Santa Fe, Tenn., March 29, 1881.

Losses. - I congratulate the editor on the success of the Weekly. If I get it in the morning I cannot stop till I scan in the morning I cannot stop the I scatt it all over. My pets, I fear, will all die. Out of 33 only 11 survive; one is queenless but strong in bees and honey. My beautiful Italian which I found nearly beautiful Italian which I found nearly dead and put in a queenless colony is gone with all in the colony. One I covered with 2 thicknesses of wool carpet did well till March, and died with plenty of honey. We have snow with north winds now. I fear more will be dead when this breaks up. Those I wintered in the shed fared better than those out. Some lose  $\frac{1}{12}$ ; some all.

G. W. Ashry.
Valley Station, Ky., April 2, 1881.

Unward Ventilation.—As there have been so many conflicting reports in regard to bees wintering the past winter, I thought I would mention a circumstance that came under my observation while at a sale a few days ago. There sumed honey to keep warm on the same while at a sale a few days ago. There principle that a snall stove requires a great amount of wood to keep a large room warm. The great loss of bees colonies had all stood out on the sum-

the hives, where they were left on all winter, and although they did not lit very closely and the bees had plenty of apward ventilation, the bees were in apoward ventuation, the bees were in good condition. It occurred to my mind that there must be more in upward ven-tilation than many supposed, for some have died around here that were all packed in chaff, and appeared to be in good condition last fall. I am a strong advocate for chaff-packing, but what is the use of chaff-packing if we can get as good results by having plenty of ward ventilation and a vacant chamber above the bees?

J. A. OSBORNE. above the bees? J. A. C. Rantoul, Ill., April 6, 1881.

Italians vs. Black Bees.—My bees are mostly blacks and hybrids, and I have lost heavily. I have one colony of Italians which endured the severity of the winter much better than the blacks. I think the Weekly BEE JOURNAL splen-did, and am glad that it is a success. J. A. McKee.

Sparta, Ill., March 15, 1881.

Bees in California.—Honey is coming a fast; the bees are working in sec-Bees in Caifornia.—Honey is coming in fast; the bees are working in sections and capping; drones are hatching and flying out. I have kept back swarming by great exertions. I have 20 frames and sections on some, and 2 tiers of sections on others. The bees are building out foundation, and the weather is fine and dry, but the nights are cool. One colony with a hybrid queen had the boxes all capped on the 4th and has built out several combs of 4th, and has built out several combs of foundation of last year's make. I find that my bees will bite off the bottom and corners to build out drone comb. and corners to build out drone comb. My colonies are strong in bees and working nicely. A queen 3 years old is the only one I have had superceded. I have grapes and fruit with 60 colonies of bees within a stone's throw; I have observed closely but never found a bee bitting the fruit. I had a feature of biting the fruit. I had 2 frames of foundation worked out and tilled with eggs, pollen and honey in 20 hours. J. D. ENAS.

Napa, Cal., March 30, 1881.

My Plan of Wintering.—My bees are in fine condition on their summer stands, notwithstanding the very cold the condition of the very cold that it was the Quinby hive. The stands, notwithstanding the very con-winter. I use the Quinby live. The plan that I have adopted for wintering for the last 3 years is to take off the cap and honey board, put 3 sticks across the frames, then a quilt over the frames, then also consider for some states here. then old carpeting (or some other por-ous article) and keep warm and dry; after which I place a rough box with from 2 to 4 inches of air-space all around the hive, with an entrance the same as in the hive. In this way I have suc-ceeded for 3 winters with the loss of but one colony. They had a good flight but one colony. They had a good flight in February and also in March. I shall have to feed some now. Last season was a poor one for honey. There are comparatively but few bees in this visitive, they have wintered fairly well cinity: they have wintered fairly well.
I very highly prize the Weekly Bee
JOURNAL. EDEN DAVIS. Thompson, Conn., April 5, 1881.

Bees in Vermont. - We have had about bees in vermoni.—We have had about 90 days of uninterrupted sleighing. Bees here that were properly cared for and put into cellars are, as far as I can learn, in good condition. I had 3 colonies that exhibited signs of dysentery, but had the good fortune to be able to give them a flight early in Followsen. out had the good fortune to be able to give them a flight early in February, and they are all right now. I hope to come out without loss. During the past two years my average has been about 25 two years my average has been about 25 lbs. of extracted honey per colony; this sells readily for 1 shilling per lb., put up in quart fruit jars. Are tin pails a good receptacle for honey? Is not the cheap tinware adulterated with lead? and would not honey put up in such packages be injurious to the health of the consumer?

W. S. Clark.

Rellows Falls Vt Bellows Falls, Vt.

[Tin pails, which can be utilized in the house after the honey is used, make good receptacles. Only soured honey, we think, would be liable to absorb lead

Great Loss of Bees.-Never before in the recollection of bee-keepers have bees become so nearly extinct as now in our vicinity. Last fall no less than 300 colonies of the useful pets decorated the yards of our neighbors. At this date about 292 colonies are no more. Very little attention was given to the little fellows. Out of 30 extra colonies I have but one colony remaining to mourn the loss of their industrious neighbors.

E. J. HINSHAW. neighbors. E. J. L Lynn, Ind., April 1, 1881.

Bees Confined 134 Days.—I am wintering 170 colonies of bees. The greater part of them are in the cellar and are doing well. They have not seen daylight for 134 days, and are not likely to for several days to come, as it has been snowing steadily for the last 60 hours. Sleighing is pretty fair here and the snow is at least 20 inches deep where not drifted, and the drifts are from 2 to 6 feet high. What is the correct pronunciation of the name Dzierzon?

S. F. NEWMAN.

Norwalk, O., March 31, 1881.

Norwalk, O., March 31, 1881.

[It is pronounced thus: "Tseerson." -Ep.1

Colonies Strong.—I put 59 colonies of bees in the cellar; 4 of which were made late of nuclei; I lost 2 of them; the balance consumed about 5 lbs. per colony while in the cellar. They are now stronger than ever before at this time of the year. Molle O. Large.

Millersville, March 29, 1881.

Shall I Transfer or Drive Them?—I bought at a sale a few days ago 2 colonies of black bees, one in an old gum and the other in an old box hive. The combs look very black and old. Which combs look very black and oid. Which is the better plan, to transfer, or drive into a new hive filled with foundation, and Italianize in either case? Please answer in next issue of BEE JOURNAL.

W. R. YOUNG.

Myersville, Md., March 29, 1881.

[Transfer, by all means. You will need the brood in the old combs (which would be lost in the case of driving) as fast as hatched to nurse the Italian brood, it being the especial province of the younger bees to do the nursing and other drudge work in the hive. It is an easy matter, as the season advances, to work the old combs out, by putting in a sheet of foundation every few days in the centre of the brood nest, crowding the old combs to the outside, and lifting out as fast as emptied of brood.—ED.]

Heavy Loss in Bees .- Bees are nearly all dead in this locality; one who had 24 colonies last fall has 3 left; another with 10, has 2; another with 30, has 5 or while others having I to 10, are all dead. I have 2 out of 20, but cannot do without the Weekly BEE JOURNAL. "Long may it live."

M. F. EASTMAN. Queensville, Ind., April 2, 1881.

Bees in Good Condition.—I am well pleased with the Weekly BEE JOURNAL. My bees have come through the winter my bees mave come imough the winding good condition. I had them packed in chaff on the summer stands. Bees left unprotected are, I think, about half dead in this locality. I lost all my bees 2 years ago, by wintering without pro-tection. After losing all I bought more 2 years agonometer tection. After losing all I bought more and wintered in the cellar with success. I like packing in chaff the hest; they come through in better condition. Success to the AMERICAN BEE JOURNAL. Boswell, Ind. J. H. McDaniel.

Bees Confined 6 Months. — March ade us "adieu" with a regular bade us "adieu" with a regular howler from the northwest, and 10-below zero. Snow in the timber is about 2 feet deep; bees have been confined since the middle of Oct.; ice in the lake is 3 feet thick. The way things now look bees will be confined to their hives 6 months. What do they think of that "down south" complain-ing of long confinement; while their bees are at work on the clover and fruit

death? This winter has been a terror, and if the Palestine bees are proof against death from cold, I want them. I do not wish to complain, for my bees 7 do not wish to compann, for my dees, 76 colonies, are all right, and bright as you wish to see. The hives are clean and they show no signs of disease. I winter in-doors, in a house made of logs arched over and covered with earth; it has a door in one end and ventilators: it is the best thing I have tried. When I get them out for good I will report their condition, etc. M.S. SNOW. Osakis, Minn., April 1, 1881.

Sawdust for Wintering .have lost nearly 13 of my bees. The greater part were packed in chaff and čut straw, in November ; the remaincut straw, in November; the remainder were put in a sawdust cellar and taken out on warm days this mouth and packed. For a winter like this a cellar for winter and packing for spring is, in my opinion, the best; but deliver me from bees in a sawdust cellar in a warm winter.

St. Charles Mich. March 30 1881 warm winter. JOEL GULICK St. Charles, Mich., March 30, 1881.

Wants the Plan.—1 should be glad if r. Robinson, of Pewamo, Mich., Mr. Robinson, of Pewamo, I would give his plan in detail for t ring queens on one comb. I think it of great importance. I am much of great importance. I am much pleased with the Weekly BEEJOURNAL,

and wish it success.

GEO. REYNOLDS.
St. Neots, England, March 15, 1881.

[Will Mr. Robinson please comply with this request ?-En.]

Bees Dead .- Most of the bees around here are dead. I have lost 4 colonies out of 14, and I expect to lose 1 or 2 more, for it is quite cold yet. I think the BEE JOURNAL the best exponent of scientific bee-culture in America. L. H. WESTPHAL.

Brighton, Mich., March 31, 1881.

A Strange Occurrence.—I have a curious circumstance to relate, and would like to know if it is of common occurnke to know if it is of common occurrence. Last spring I had a queenless colony, but with a queen cell nearly ready to cap over. One noon I found an adjoining colony about to swarm, and cutting out the queen cell, took it in the house, broke it open, and found a fully-matured queen smart and lively. noise, proke it open, and found a tuny-matured queen, smart and lively. I conceived the idea of giving it to the queenless colony, and for that purpose took a small mug, put the queen into it with a few drops of honey, put two thicknesses of common mosquito cloth ever the mag, a stick through the hanover the mug, a stick through the handle, and hung it in the queenless hive. Returning at 4 o'clock, I opened the hive and found the bees had liberated the queen, had manufactured about two square inches of comb on the stick that the mug hung on, and in nearly every cell was from 1 to 3 eggs, and the queen not out of her cell to exceed 5 hours. Is this not a peculiar instance?

J. H. Cook.

Parsons, Kans., April I, 1881.

[It is too peculiar to be possible. The bees may have swarmed from the hive alongside and taken possession of the one in which you contined the queen, or they may have had a queen when you but her in, or there may have been a fertile worker—anything is quite as probable as that a queen would be laying eggs within five hours after emerging from the cell.—ED.]

Chaff Packing Ahead. - Last fall I had 10 colonies of bees (4 in chaff hives and 6 in simplicity) all strong. The first Sunday in December was pleasant and the bees had a jollification, after which there was not a day that they could safely leave the hive until March 15 and safely leave the hive until March 15 and 16, when they had a good flight, which they very much needed. I have 7 left; 4 strong (in chaff hives) with brood; 2 comparatively strong, and one rather weak, being what was left of 2 colonies that had dysentery. All wintered on the summer stands. I think chaff hives would have saved this loss. The ground its now bare and frozen and we have had cold northwest winds for 3 days. As bees are at work on the clover and fruit cold northwest winds for 3 days. As an absence of sealed brood, threater blossoms, up here they are as still as far as 1 have been able to learn, the crowded colonies in the hive.—Ed.]

loss has not been heavy in this section. The Weekly is a positive necessity. May it "live long and prosper."
P. F. TWITCHELL.

Andover, O., March 28, 1881.

Bees and Grapes.—I noticed an arti-cle in the BEE JOURNAL for March 2d, page 68, in regard to bees and grapes. I have had both for over 10 years in one grapes, and I have the Isabella, Concord. Delaware and Augustine, and 40 colonies of bees; bees are not over 10 rods from grapes. My bees are in the cellar yet, but do not yet know how they will come through they will come through.

Thos. Pierce.
Gansevoort, N. Y., March 21, 1881.

Clinff Did It. — I commenced the spring of 1880 with 8 colonies of bees. 1 obtained 400 lbs. of honey, mostly extracted, and increased to 28 colonies. I tracted, and increased to 25 colonies. I sold one last fall and packed 27 in chaff; they are all alive up to date, 5 are rather weak, the balance are in good condition. About 13 of the bees in this part of the country are dead. C. H. WRIGHT.

Conneautville, Pa., April 2, 1881.

Are Bees Taxable?—1. I have a good deal of honey in old comb taken from box hives, with considerable bee-bread, and this honey is quite bitter in flavor—will it do to place over the brood frames to feed with? Some of the honey I think is sour.

2. Can I use old strained honey that has pollen in it to stimulate the queens? I had bees starve with sugar candy over the cluster, but not a cell of hon The candy was very hard—was that the reason they could not eat it?

4. Can bees be taxed the same as other property?

A. G. MAYHEW.

[1. The bitter honey will answer to feed over the frames. If soured, feed outside the hives, when the bees are flying freely, thus leaving it optional with them to take it or let it alone.

2. Yes.

3. Perhaps it was.

4. Yes, as other personal property. The statutes in different States vary somewhat in regard to taxable personal property.-ED.]

Bees Gone to Rest .- My bees did well last season, considering the small sup-ply of neetar yielded by the flowers. White clover and basswood, from ply of neetar yielded by the flowers. White clover and basswood, from whence we get our greatest supply, was a total failure, and our bees did not get much until fall. Our fall crop was fair. I started in the spring with 14 colonies, increased to 22 and obtained 700 lbs. of comb honey in nice shape. I packed part of my bees in chaff and the rest I covered with struct to the death of covered with straw to the depth of 2 feet, except on the fronts, which 1 covered first with a board set slanting against the hive, then a little straw over that. However, they were not prepared in this way until the last of November, with the thermometer at 20- above zero, owing to my having been away to school for 3 months. They were very strong and had plenty of honey as near as I could ascertain. But alas! when I examined them on March 5, 1 found all amined them on March 5, 1 found all quiet, after having been confined for about 125 days; there were none short of stores, but the hives were daubed badly, showing that long continement was the principal cause. Many lost \(^1\xi\_5\) some \(^2\xi\_3\) and others all. I think \(^2\xi\_3\) of the bees in this section have died, but 1 am not discouraged. I shall start anew if there are any bees to be had. Mr. Editor, do you not think the reason for bees not swarming last season was on account of a forewarming of this cold bees not swarming lists scalar was a account of a forewarning of this cold winter? Success to the Weekly Bee Journal.

A. B. Loomis. Carson City, Mich., March 4, ISSL.

[No: bees have no forewarnings any more than has humanity. The conditions were not right for swarming, either from want of honey-flow, or from an absence of sealed brood, threatening

Honey As Food.—We have just been baking honey ginger snaps, "a la Newman," as given in "Honey as Food and Medicine." We are puzzled to know how one person can embody all the rehow one person can embody all the requisites for an Editor, Doctor and Cook, and a Minister, too, by the way he quotes Scripture in this valuable little work. Perhaps he has a help-meet—as the Irishman says, "sure and hasn't he a wife?" Honey producers should always place honey before their guests, take it to fairs, ministers' donations, feetivals, sociables, exercious, old setfaste it to fairs, ministers donations, festivals, sociables, excursions, old settlers' picnics, etc., use it in the dressing and canning of fruits, and teach the people, by precept and example, that honey is good. Mrs. L. Harrison. Peoria, 1ll., April 4, 1881,

First Swarm.—Last season was very severe on bees in our State. We had rain from April until December 31, almost every day. The moth worm and the scarcity of honey in the flowers caused us to lose 25 out of 38 colonies. Our bees have been working well since the first of this month. We had a natural swarm this morning from hybrids; we put them in a Langstroth hive; they appear to be all right. Success to your Weekly. W. R. & F. P. Thompson. New Iberia, La., March 3t, 1881.

Took The Bees Out.-I have put my bees out on their summer stands. Host 8 out of 46. I had them in a room above s out of 46. I had them in a room above ground; they are out of honey now, so I must feed them, though it is cold and I fear it will injure the bees some. A word to all: see if your bees have enough honey. FAYETTE LEE. Cokato, Minn., April 1, 1881.

The Southwestern Wisconsin Bee-Keepers' Association will meet at the residence of W. B. Wallis, at Darling-

ton, Wednesday, May 11, 1881, at 10 a.m. con, Wednesday, May 11, 1881, at 10 a.m.
There will be an opportunity given for questions and answers. Interesting papers will be read, among which may be mentioned:
Location of Apiary, by E. France.
Implements of the Apiary, by R. D. Wilson.
Feeding Satracted Honey to Produce Comb Honey, by Dr. C. Abraham.
Foundation, and its Advantages, by O. R. Sylvester.
Bee Forage, by H. Gilmore.
Bee Forage, by H. Gilmore.
Preparation for Winter, by George Fox.
Wintering Bees, by Reese Powell.
Advantage to Preparing Papers, by E. France.
Produable Bee-Keeping, by E. Pike.
Produable Bee-Keeping, by E. Pike.
Profuging, will the N. O. V. Covention, on How to make the Apiary the most. Produable, by George W. House, of Fayetteville, N. Y.
A corollal invitation is given to all.
N. E. France, Sec., Platteville, Wis.

🕼 The Michigan Bec-Keepers' Association will convene in Pioneer Rooms of the State Capitol at Lansing, May 5. The following is the programme:

Regular order of business.

Annual address by Pres. W. J. Ashworth.

Address by T. G. Newman, editor of American Bee
Journal; subject, Rise, Progress, Present Condition
and Future Prospects of American Apiculture.

Essay - Profitable extent of bee-keeping, by James
Heddon, Dowagiac.

Essay - Requisites of an Apiary, by II. A. Burch,
South Hayen.

Essay-Some important facts in bee-keeping, by
Prof. A. J. Cook, Michigan Agricultural College.

Discussions and remarks.

Examination of exhibits.

All exhibitors of suppiles are requested to send
samples to the Secretary, with prices and descriptions attached, and all transpartation charges must
be prepaid by the exhibitors. Geo. L. Perry, Sec.

Programme of the Northwestern Bee-Keepers' Union, to be held at Hastings, Minn., May 17, 1881:

1.—Address of Welcome, by J. N. Senris. 2.—Reports of committees. 3.—Reports from all—number, kind and condition

2.—Reports of committees,
3.—Reports of rom all—number, kind and condition of bees,
4.—A paper by Pres, A. Tidball, on honey-producing plants and flowers.
5.—A paper by Dr. P. Barton, of St. Paul, on honey as food and medicine.
6.—A planty culture and our fairs, by Hon. William Avery, of St. Croix Fails, Wis.
7.—A paper on sales of boney, by F. D. Dorotby, of Taylor's Fails, Minn.
8.—A paper on wintering bees, by L. Day, of Farmington.
9.—Progressive bee-culture, by J. G. Teter.
The above subjects will be open for discussion. Jaudition to the above, the following subjects are suggested:

Pasiential properties of a good bee hive.

gested:

1.—Essential properties of a good bee hive.

2.—How to prevent and cure foul brood.

3.—How to prevent spring dwindling.

4.—Comb Foundation, with dividing and natural swarming.

Appointment of committees.

Election of officers. Adjournment.

13 All bee-keepers are cordully invited. Entertument free.

F. B. DOROTRY, Sec.

The North Western Wisconsin Bee-keepers Association will meet at Germania Hall, LaCrosse, Wis., on Tuesday, May 10, at 10 a. m. All interested in bee-keeping are requested to be present. L. H. Pammel, Jr., Sec.

## SPECIAL NOTICES.

Single copies of the JOURNAL are sent postage paid for 5 cents each.

Those who may wish to change from other editions to the Weekly, can do so by paying the difference.

We have prepared Ribbon Badges for bee-keepers, on which are printed a large bee in gold. Price 10 cents each, or \$8.00 per hundred.

Notices and advertisements intended for the Weekly Bee Journal must reach this office by Friday of the week previous.

Instead of sending silver money in letters, procure 1, 2 or 3 cent stamps. We can use them, and it is safer to send such than silver.

Grav Hairs Are Honorable but their premature appearance is annoying. Parker's Hair Balsam is popular for cleanliness and promptly restoring the vouthful color.

The date following the name on the wrapper label of this paper indicates the time to which you have paid. In making remittances, always send by postal order, registered letter, or by draft on Chicago or New York. Drafts on other cities, and local cheeks, are not taken by the banks in this city except at a discount of 25c., to pay expense of collecting them.

Premiums.—For a club of 2, weekly we will give a copy of "Bee-Culture;" for a club of 5, weekly, we will give a copy of "Cook's Manual," bound in cloth; for a club of 6, we give a copy of the Journal for a year free. Do not forget that it will pay to devote a few hours to the Bee Journal.

At the Chicago meeting of the Na At the Chicago meeting of the National Society we were requested to get photographs of the leading apiarists, to sell to those who wanted them. We can now supply the following at 25 cents each: Dzierzon, the Baron of Berlepsch, and Langstroth. The likeness of Mr. Langstroth we have copied, is one furnished by his daughter, who says, "it is the only one ever taken when he was in good health and spirits." We are glad to be able to secure one of such a satisfactory nature. a satisfactory nature.

Sample copies of the Weekly BEE JOURNAL will be sent free to any names that may be sent in. Any one intending to get up a club can have sample copies sent to the persons they desire to interview, by sending the names to this office.

It would save us much trouble, if all would be particular to give their P.O. address and name, when writing to this office. We have several letters (some inclosing money) that have no name. Many others having no Postoffice, County or State. Also, if you live near one postoffice and get your mail at another, be sure to give the address we have on our list.

We can supply but a few more of the back numbers to new subscribers. If any want them, they must be sent for

Constitutions and By-Laws for local Associations \$2 per 100. The name of the Association printed in the blanks for 50 cents extra.

The Volume of the BEE JOUR-NAL for 1880, bound in stiff paper covers, will be sent by mail, for \$1.50.

When changing a postoffice ad-ress, mention the old address as well as the new one.

## CLUBBING LIST.

We supply the Weekly A merican Bee Journal and any of the following periodicals, for 1881, at the prices quoted in the last column of figures. The first column gives the regular price of both :

Publishers' Price. Club.

Weekly Bee Jonrnal (T. G. Newman) \$2 00 it Gleanings in Bee-Culture (A.I. Root) \$3 (0, 2.75) Bee-Keepers' Magazine (A.J. King), \$3 00. 2.60 Bee Keepers' Exchange (J.H. Nellis), \$2.75, 2.50 Bee-Keepers' Instructor (W.Thomas) \$2.50, 2.55 Bee-Keepers' Ginde (A.G. Illi), \$2.50, 2.55 The 5 above-named papers, \$3.55, 5.50 Prof. Cook's Manual (bound in cloth) \$3.50 Bee-Keepers' Ginde (A.G. Illi), \$2.50, 2.55 Semi-monthly Bee Jonrnal, \$4.50 Dess

For Seml-monthly Bee Journal, \$1.00 less. For Monthly Bee Journal, \$1.50 less.

# Honey and Beeswax Market.

BUYERS' QUOTATIONS.

### CHICAGO.

CHICAGO,
HONEY—The market is plentifully supplied with
honey, and sales are slow at weak, easy prices. Quotaile at 186230; for strictly choice white comb in 1
and 21b, boxes; at 146416; for fair to good in large
packages, and at 19612c, for common dark-colored
and broken lots. Extracted, 8c. 10c.
BEESWAX.—Choice yellow, 20g/23c; dark, 15@17.

# NEW YORK.

HONEY.—Best white comb boney, small neat packages, 14s/16s; fair do, 14s/16s; dark do, 14s/12; herge boxes sell for about 2c, under above. White extracted, 2g/10c; dark, 7gSc; southern strained,

BEESWAX.- Prime quality, 20@23c.

# CINCINNATL

HONEY.—The market for extracted clover honey s good, at 86410c. Comb honey is of slow sale at 16c. good, at 8@10c. Comb or the best. BEESWAX—I8@22c. C. F. MUTH.

# SAN FRANCISCO.

SAN FRANCISCO.

HONEY.—Since our last there have been some 1,000 cases more of extracted honey cleared for Laverpool, and at our last the outlook for the coming crop was very poor. Since, there have been copious showers, and reports are generally more favorable. We quote white comb, 126/136; dark to good, 90:011c. Extracted, choice to extra white, 55:26/2c.; dark and candied, 56:65-6c.

BEESWAX—226/2246c., as to color.

STEARNS & SMITH, 425 Front Street.
San Francisco, Cal., March 31, 1881.

A Smooth Complexion can be had by every lady who will use Parker's Ginger Tonic. For promptly regulating the liver and kidneys and purifying the blood there is nothing like it, and this is the reason why it so quickly removes pimples and gives a rosy bloom to the cheek. See police cheek. See notice.

My Annual Catalogue of Vegetable and Flower Seed for 1881, rich in engravings from photographs of the originals, will be sent FIEE to all who apply. My old customers need not write for it. I offer one of the largest collections of vegetable seed ever sent out by any Seed House in America, a large portion of which were grown on my six seed farms. Full directions for cultivation on each package. All seed warranted to be both fresh and true to name, so far, that should it prove otherwise, I will refill the order gratis. The original introducer of the Hubbard Squash, Phinney's Melon, Marolehead Cabbares, Mexican Corn, and scores of other vegetables. I invite the patronage of all who are anxious to have

12m5 JAMES J. H. GREGORY, Marblebead, Mass

HONEY WANTED.—I desire to purchase sev-of light; also, Comb Honey. Those having any for sale are invited to correspond, giving particulars.

ALFRED II. NEWMAN 972 West Madison street, CHICAGO ILL.

# Wire Nails.

There being considerable demand for wire have concluded to entry a stock of them, and can fill orders for any quantity promptly. For muling Sec-tions, Cases, Frames, Rucks, Crates, &c., they have become quite popular.

The entire length of the nail being the same thick-

ness, they never loosen as ordinary iron mills will, and are not as liable to bend or break.

From the assortment of lengths given in the table below, any kind of nailing may be done with these onlis, even to making large buxes.

# Books for Bee-Keepers.

Cook's Monaul of the Aphrey,—Entirely rewritten, greatly enlarged and elegantly illustrated, and is fully up with the times on every conceivable subject that interests the uplarist. It is not only in structive, but intensely interesting and thoroughly practical. The book is a masterly production, and one that to bee-keeper, however limited his means, can afford to do without. Cloth, \$1.25; paper covers, \$1.00, postpaid. Per dozen, by express, cloth, \$12; paper, \$9.50.

Quinby's New Bee-Keeping, by L.C. Root.— The author has treated the subject of hee-keeping in a manner that cannot full to interest all. Its style is plain and forcible, making all its readers sensible of the fact that the author is really the master of the subject. Price, \$1.50.

Novice's A B t'of Bee-Culture, by A. I. Root. This embraces "everything pertaining to the care of the honey-bee," and is valuable to beginners and those more advanced. Cloth, \$1.25; paper, \$1.00.

King's Bee-Keepers' Text-Book, by A. J ling.—This edition is revised and brought down to be present time. Clotb, \$1.00; paper, 75c.

Langstroth on the Hive and Honey Hee This is a standard scientide work. Price, \$2.00.

This is a standard scientific work. Price, \$2.00.

Hiessed Hees, by John Allen.—A romance of bee-keeping, full of practical information and contagious enthusiasm. Cluth, \$1.00.

Hee-Culture; or Successful Management of the Apinry, by Thomas G. Newman.—This pamphlet embraces the following subjects: The Location of the Apinry—Honey Plants—Queen Rearing —Feeding—Swarming—Dividing—Transferring-Italianizing—Introducing Queens—Extracting—Quieting and Handling Bees—The Newest Method of Preparing Honey for Market, etc. It is published in English and German. Price for either edition, 40 cents, postpaid, or \$3.00 per dozen.

Food Adulteration: What we eat and should

Food Adulteration; What we cat and should not cat. This book should be in every family, where to onght to create a sentiment against the adulteration of food products, and demand a law to protect consumers against the many health-destroying adulerations offered as food. 200 pages. Paper, 50c.

The Dzierzan Theory;—presents the funda-nental principles of bee-culture, and furnishes a condensed statement of the facts and arguments by which they are demonstrated. Price, 15 cents.

which they are demonstrated. Price, 15 cents.

Honey, as Food and Medicine, by Thomas o. Newman.—This is a pample tof 24 pages, discoursing a nature, quality, sources, and preparation of the foot the Market; Honey as an article of food, giving recipes for making Honey Cakes, Cookies, Puddargs, Found, Wines, Ac.; and Honey as Medicine, followed by many useful Recipes. It is inteeded for consumers, and should be scattered by thomsands all over the country, and thus assist in creating a demand for honey. Published in English and German. Price for either edition, 6c.; per dozen, 50c.

Wintering Bees.—This pamphlet contains all the Frize Essays on this important subject, that were read before the Centennial Bee-Keepers' Associa-tion. The Frize—425 in gold—was awarded to Prof. Cook's Essay, which is given in full. Price, 10c.

The Hive I Use-Being a description of the hive used by G. M. Doolittle. Price, Sc.

Extracted Honey; Harvesting, Handling and Marketing.—A 24-page pamphlet, by Ch. & C. P. Dadant, Handliton, iii. This gives in detail the methods and management adopted in their spiary. It contains many good and useful bints, and is well worth the price—15c.

Practical Hlutto Bee-Keepers, by Chas. F. Muth. Cincumati, Ohio; 32 pages. This pamphlet gives Mr. Muth's views on the management of bees, and embraces several of his essays given at Conventions, etc. It will be read with interest by beginners as well as those more advanced in the science of beeculture. Price, 10c.

Kendall's Horse Book—No book can be more useful to borse owners. It has 35 engravings illustrating positions of sick boses, and treats all diseases in a plant and comprehensive manner. It has a large number of good recipes, a table of doses, and much other valuable horse information. Paper, 25c.

Chicken Cholera, by A. J. Hill,—A treatise on its cause, symptoms and cure. Price, 25c.

Moore's Universal Assistant contains information on every conceivable subject, as well as receipts for almost everything that could be desir of We doubt if any one could be induced to do without it, after having spent a few hours in looking it through. It contains 1016 pages, and 500 cogravings. (Oth., \$2.56.

Rapp's Easy Calculator.—These are handy tables for all kinds of merchandlise and interest. It is really a lighting calculator, nicely bound, with slate and pocket for papers. In cloth, \$1.00; Morocco, \$1.50. Cheap edition, without slate, 50c.

Sent by mail on receipt of price, by

# The Lessons from our Losses.

EUGENE SECOR.

On Nov. 5 I put my bees in the house On Nov. 51 put my bees in the house cellar, used as most house cellars are for storing vegetables, apples, soup-barrels, etc. To-day I have removed them to their summer stands, making 153 days, or a little over 5 months, constant continement. I found 6 dead out of 22 put away in the fall. The conditions favorable to successful wintering were: total darkness freedom from from the week.

put away in the fall. The conditions favorable to successful wintering were: total darkness, freedom from frost when put away, a frost-proof cellar, good ripe honey in the hives and comparative quiet during the winter.

Unfavorable: cellar probably too warm at times, slight disturbances by going in with a light for vegetables, and lack of proper ventilation.

The fatality among the bees in this neighborhood is almost unprecedented: one party is said to have lost 78 out of 80 (ont-doors); another all (in cellar); another 50 per cent., in cellar; all were experienced bee-men. Nearly all others' bees are dead. I estimate that 80 per cent, of all bees within the range of the clover field. Have we learned anything from this severe experience? Many, I believe, have not, they think it is all luck anyhow. Others know better than practice. Hence losses are likely to continue to occur, and the market will never be overstocked unless the enterprising grocer with his glucose pot comes to the rescue of the over-worked bee.

I indorse what Mr. Doolittle says in

We had at least 4 months in which a hee could not have lived a minute away from the hive. If out-of-doors the necessity of a flight being increased by the increased amount of honey consumed, death was almost sure. The same in cellars if the proper conditions were not present—even and suitable temperature perfect darkness and quiet, and ripe honey. With these the little pets will stand a long siege from old Boreas.

Forest City, Iowa, April 8, 1881. We had at least 4 months in which a

For the American Bee Journal.

## The Italian not a Pure Race.

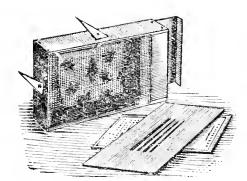

G. W. DEMAREE.

It seems a little strange that it has not occurred to some of our brother bee-keepers that their discussion of the merits of the light and dark "strains" of the Italian honey bee furnishes all the evidence necessary to prove them a mixed race of bees.

weather had permitted a flight in February I think nearly all would have lived.

that the race is a hybrid or cross? Such results as I have named (though put in a more moderate form) would be simply a more moderate form) would be simply impossible if the race was pure. If you will try your skill on the German or common bee you will find that no amount of selection will give any perceivable change in their appearance. Therefore, we conclude that the Italian bee is a cross between a pure yellow, quiet race, and a pure black, irritable race of bees, both of which are now unknown except as found promiscuously in the Italian variety.

Perhaps it is the happy combination of these two races that gives the Italian its peculiar value, and when we have ascertained what proportion of blood of these two races when combined gives the best results, and have bred our bees up to that standard, we will have perfected Mr. Newman's Apis Americana. It seems to be conceded on every hand It seems to be conceded on every hand that the Italian race becomes lighter in color simply by being imported to, and multiplied in this country. For one, I do not believe this. If they are bred promiscously, i. e., without selection as to color, there is no reason why the result in this country should be different

PEET'S QUEEN CAGE.

the Italian honey bee it is impossible that the race as a whole can be pure. that the race as a whole can be pure. The idea of two or more varieties existing in any one thing promiscuously, and still the thing be pure and unmixed, is the height of absurdity. We are tempted to ask, what is meant by the dark and light strains of the Italian? and, at what point is the dividing line to be fixed? My experience is that there are about as many different shades of color (if nicely drawn), as there are colonies of Italians. The general appearance may be the same in some colonies, but upon a close examination in pearance may be the same in some colonies, but upon a close examination in all their parts a difference is discernable. You may select an imported queen and rear daughters from her and some of her progeny will be darker than others. Now if you select the lightest one amongst them and breed from her, carefully continuing the selection, it is possible to reach the beautiful type known as "Albinos," while on the other hand, by the same careful selection of the darkest bees to breed from, you can breed every tint of yellow out I indorse what Mr. Doolittle says in the Bee Journal of April 6 in relation to confinement and dysentery. I regard him as sound on this question, as on any other which he discusses. What bees I lost died of dysentery and had they been confined 30 days longer undoubtedly another 30 per cent would have gone the same way, while if the

If there are two or more varieties of from what it would be in their native home. Climatic causes work too slow to produce any perceivable effects in a

to produce any perceivable effects in a few years of time.

It is careful selection that has given us our beautiful superior bees rather than the purity of the stock from which we have usually made our selections. The readiness and rapidity with which the Italian race or variety will assume new types or "strains" under the manipulating hand of the careful breeder, can be explained on no other hypothesis than that the race is an amalgamation can be explained on no other hypothesis than that the race is an amalgamation of blood more or less fixed by long secusion in their native home. It is truly amusing to see the ingenious efforts put forth by some of the advocates of "purity of the race" to evade the force of these conclusions, and counteract the growing tendency to accept them as true. That there are black bees in Italy no one who is willing to trust to his own senses can doubt, unless the vendors of queens in that country have sent all their black bees over here; for all of us have seen black Italians among our imported stock. our imported stock. Christiansburg, Ky.

For the American Bee Journal. In-Door Flying for Dysentery.

WM. H. FRANCIS.

An artificial, or in-door flying for An artificial, or in-door flying for dysentery is not entirely new, and yet, notwithstanding the heavy losses reported from all quarters during the past winter, I have seen no account of this remedy having been resorted to, nor have I seen it recommended. I have recently given it a practive therefore

nor have I seen it recommended. I have recently given it a pretty thorough test and for the benefit of bee-keepers hereafter I will give the result.

I commenced bee-keeping last spring and went into winter quarters last fall with 13 colonies. Early in February several of them began to show signs of dysentery. I watched them closely and in 2 or 3 weeks 2 of the hives were so badly soiled around the entrances that I had but little hope of saving them unless a remedy could be found. I searched my bee-books and the only remedy I found was the cage method of giving an in-door flight mentioned in remedy I found was the cage method of giving an in-door flight mentioned in the A B C of Bee-Culture. I made a cheap cage and tried it on the colony that appeared to be in the worst condition, but was not satisfied with the result and abandoned it.

Thus or 2 days after this one of my

Two or 3 days after this one of my bee-keeping neighbors told me that he Two or 3 days after this one of my bee-keeping neighbors told me that he had just given 2 or 3 colonies a flight in a small room without a cage, and considered it a success. I had seen the statement in some of my bee-literature that if bees were released from their hive in a room they would not return, but I determined to give it a trial. I therefore selected a small bed-room in the south part of my house through which a stovepipe passes, and having but one window, looking south. After removing the furniture I covered the carpet with newspapers and protected the wall around the window and as much of the window casing as I could in the same manner. The temperature of the room when closed ranged from 60- to 80- F., according to the weather and the quantity of heat furnished from the stove below. Towards noon I carried a hive up and placed it on the floor, the stove below. Towards noon I carried a hive up and placed it on the floor, about 3 feet from and fronting towards the window. I opened the entrance, removed the cap and covered the frames removed the cap and covered the traines with a newspaper having an opening 2 or 3 inches in diameter through the centre. The paper was to prevent the bees spotting the hive, and the opening to allow the bees to pass out at the top as well as at the entrance. The result was entirely satisfactory. During the as well as at the entrance. The result was entirely satisfactory. During the warmest part of the day the roaring of the bees could be heard through all parts of the house. On going into the room towards sunset 1 found the bees nearly all quieted down in the hive. The few that remained clustered about the window were easily brushed off on a newsmaper and returned to the hive

the window upon the floor they would return to the hive themselves. By this method I have given all my bees a flight, have given them a thorough examination, and they are now all in good condition, apparently able to remain in the cellar if need be until the middle of May.

When wouldn't it never you beckeeper

a newspaper and returned to the hive. I afterwards found that if brushed from

Why wouldn't it pay every bee-keeper in cold latitudes to have a room for this purpose in connection with his apiary?

A small room would do, and one large window would probably be better than 2 or 3 small ones. A large room to be window would probably be better than 2 or 3 small ones. A large room to be used for other purposes ordinarily might be so provided with windows that it could be divided by means of cheap temporary partitions into several small rooms, and in this way several colonies could fly at the same time, and thus large as well as small bee-keepers could avail themselves of this remedy whenever necessary.

whenever necessary.

Such winters as the past are rare, but when they do come thousands of colonies might be saved with but little

tronble and expense.

For the American Bee Journal.

# Bee-Keeping in Kentucky.

W. WILLIAMSON.

The general reports throughout Kentucky are very discouraging to beekeepers in general; in fact the past 2 seasons have been failures. In some localities a few beekeepers have brought their bees through the present severe winter without loss owing no severe winter without loss, owing no doubt to a full supply of honey in the brood chambers, and being fully protected from the cold winter blasts. All should, however, take courage, as the coming season may be one of a bounti coming season may be one of a bountiful supply of honey and swarms which will amply repay them for the failures of the past. All empty combs should be carefully cleaned off and laid away for future use, as, if broodchambers are filled with these empty combs, and swarms put in them in May, they will often thrive better and store more honey than the parent colony. All colonies should now be fed up (whenever the day is mild) to induce early breedonies should now be fed up (whenever the day is mild) to induce early breeding. A little rye-meal should be placed in convenient places to take the place of pollen. Nothing should be left undone in the early spring that will tend to strengthen and build up weak colonies. It is not necessary to feed honey to bees—a good syrup made of sugar, water, and a little flour, makes excellent feed. It can either be fed as a syrup or made into candy. From all reports that I have been able to obtain, the loss of bees in Kentuncky this winter will be fully \( \frac{1}{2} \), and if the remainder are will be fully ½, and if the remainder are not fed up early, fully a third more will perish for want of supplies.

## What Is Royal Jelly?

Lexington, Ky.

W. C. PELHAM.

article under the above cap tion, published in the BEE JOURNAL of March 23, your correspondent makes some very broad assertions to support his theory of the development of queens.

For instance he says: "The fertile nist nearly of the development of queens. For instance, he says: "The fertile workers are produced by the workers taking the drone's semen into their stomachs," etc. If your correspondent would state just how he discovered that it would be of interest to your readers.

Just what constitutes the royal jelly may be hard to determine, but we might settle whether or no it differs mater-ially from the food given workers and drones by collecting enough of the lat-ter to supply a queen cell, and hatching it, if necessary, in a lamp nursery. That the eggs do not differ in character from which workers and queens are produced is well established. If the eggs are the same up to the time of their hatching, there can be no way to produce queens except by nutrition, growth, development. The idea that the ovary of the bee can be fecundated while in an undevoloped state is not in accordance with physiological laws as now known. I will venture to assert that no instance can be named in the

much practical importance, I will suggest how your readers may try some ex-periments, the results of which may be of interest to scientific bee-keepers and

the world at large.
1st. Substitute a drone egg for worker egg in a queen cell naturally built, and if necessary seal it artificially

and hatch it in a lamp nursery. (See Langstroth on this experiment).

2d. Supply a worker egg with worker food collected from the cells so that it may be as abundant to the larva as royal jelly is.

2d. Supply a drone egg in like man-

3d. Supply a drone egg in like man-

ner.

These last two may be varied by collecting the food from drone cells. I do not think it beyond the possible to hatch a bee egg and nurse the larva during growth in an artificial queen cell. It would probably require to be capped or sealed over at the proper age. I have noticed that the bee larva it unsealed and removed from the care of the bees. and removed from the care of the bees work out of the cells and fall off the combs. The sealing may, there-fore be merely to confine them to the

## My Experience with Separators.

G. M. DOOLITTLE.

We read on page 33, AMERICAN BEE JOURNAL, 1881, these words from the pen of Mr. Heddon: "These separators pen of Mr. Heddon: "These separators cost me too great a portion of my surplus crop, to say nothing of their first cost and trouble of manipulating;" and again, "there is no need of those misances called separators." On page 75 of the Bee Journal we read, also, "that all separators are a great drawback to the production of comb honey" "that all separators are a great draw-back to the production of comb honey." Now, this all sounds good, and if there were no other bee-keepers in the United States except himself, no doubt all would be well. But it happens that myself and others keep bees; it also happens that all honey districts are not like his, and that different methods are used to secure certain results, by dif-ferent parties; hence, the only true way to arrive at a right conclusion is to watch and see what methods the successful ones adopt.

I believe tin separators are right the

opposite of a nuisance; that they do not cost us a pound of our surplus crop after they are bought, and that they are no drawback to the production of comb honey, but, on the contrary, a help. Now for my reasons for such a belief: first used separators in 187 small scale, to try the feasibility of them. These were cut so as to leave 1/2 an inch at the top and bottom of the sections, as we were sure they would retard the labor of the bees in the boxes. inasmuch as they divided the bees into small clusters apparently. To test the small clusters apparently. To test the matter, we used some without separa-tors, and went so far as to leave the bottoms pretty much entirely off some boxes, to see how much the gain would he; but at the end of the season each was about balanced as regards the surwas about balanced as regards the surplus. We found we had made a blunder in cutting our tin too narrow. The next year the tin was cut wider, and also some were slotted so as to divide the bees as little as possible. Some were used with, and some without separation. arators. No perceivable difference as to yield was the result, while many of those without separators could not be crated, to say nothing of glassing them. We finally adopted a separator as wide as the inside of the box within <sup>1</sup><sub>4</sub> inch at the top and bottom, with no perfora-tions of any kind, and to-day, although we have experimented many ways since then, we see no reason for abandoning them; but on the contrary, many rea-sons for still continuing their use, a few

it is snow white, and not leave it on the hive till all are finished. Now, if we do this, taking out  $^1{}_3$  or more, and place those partly filled, or empty except a to my statements about foundation, starter, in their places, unless separators are used the bees will lengthen the cells of those farthest advanced, so as to crowd into the others, thus making irregular combs, as we have in putting empty frame between two full ones in the brood chamber.

Third, by the use of cases with separa-Third, by the use of cases with separators, we need take none of the precautions about "adjusting," which Mr. Heddon told Mr. Tuttle about, but simply slip our boxes into the cases, clamp them together, and no further trouble. We should want to use cases anyway, to keep the boxes clean and free from propolis, if nothing more, and should consider the plan of letting the bees go over the hottoms and tops of the boxes. over the bottoms and tops of the boxes, as given on page 75 of the BEE JOUR-NAL, a bad one.

One other thing: I see, in order to get these straight combs, Mr. Heddon uses comb foundation, and as most of us must buy it, we have to take the pennies which we have loarded up for the supwhich we have hoarded up for the support of our families, and send them away to some supply dealer, to encourage him in getting a living in that way instead of producing honey for market. I am glad Mr. Heddon does not sell foundation, for if he did we might think he was throwing away tin separators for other supply dealers to "grind their axes on," while he ground his on the more prolitable "comb foundation" (see Bee Journal, page 66). Please excuse me for joking.

Lembarked in the bee business with

I embarked in the bee business with the understanding that I paid out no money for extras or lucuries, and from my experience with comb foundation I still consider it a luxury, believing that we can produce comb from the bees at a less expense than it costs us to buy foundation, and thus keep our pennies foundation, and thus keep our pennies at home. Again, our honey comes with a rush, as a rule, and the bees seem to prefer to add their own wax on to the foundation, rather than to draw the foundation out, with the one exception of the thim Van Densen. I have repeatedly scraped the cells and honey off of the lozenge-shaped foundation, washed the foundation, and presented such a piece, together with a piece of the same that had never been used, to parties to have them tell which the bees the same that had never occurred parties to have them tell which the bees had used, and it was with difficulty that the contraction of the found. With any difference could be found. With the Van Deusen the case is different, for in order to make the flat bottoms lozenge-shaped, the bees must manipulate it. But this manipulation costs the late if. But this manipulation costs the bees time, hence the flat-bottomed is not as readily accepted by the bees. Where not more than 2 or 3 lbs. of honey Where not more than 2003 108, of honey is stored in a day, the bees generally thin the foundation properly; but if a greater yield, the wax in the foundation is little used, the bees merely using their wax to lengthen the cells with. At least such is my experience with foundation of prayions shades for the foundation of various shades for the

foundation of various shades for the past 5 years.

Once more: From experiments made each year for the last 5 years, I have been unable to see wherein any gain was made in our honey crop by the use of foundation. We have repeatedly placed boxes filled with foundation, and those having a starter of natural comb to the amount of not more than three square inches, side by side, and as a rule, the box with the starter of comb would be filled ready to be taken off first. We also have failed to notice any greatly increased yield by the use of foundation, reported by any one. To sum up, from experience and observation up to the present time, we believe comb foundation does not, all things considered, pay when used in section boxes; that section when used in section boxes; that section boxes cannot be used to the best advantage without tin separators; that the while in an undevoloped state is not in accordance with physiological laws as sons for still continuing their use, a few now known. I will venture to assert that no instance can be named in the whole animal creation where the female is impregnated by means of the digestive organs. To each set of organs in the animal economy is assigned their functions and the functions of one set cannot be assumed by another set in the manner that Mr. R. indicates.

While a knowledge of the composition of the royal jelly may not be of the foundation.

While in an undevoloped state is not in sons for still continuing their use, a few of which we will give you.

First, we wish to work our sections which the secations (which the separators is no greater than filling the sections (which the separators will cover) once full of foundation, and that after the tin separators will cover) once full of foundation, and that after the tin separators will cover) once full of foundation, and that after the tin separators will cover) once full of foundation, and that after the tin separators will cover) once full of foundation, and that after the tin separators will cover) once full of foundation, and that after the tin separators will cover) once full of foundation, and that after the tin separators will cover) once full of foundation, and that after the tin separators will cover) once full of foundation, and that after the tin separators will cover) once full of foundation, and that after the tin separators will cover) once full of foundation and the functions of one set can be secured in that way. If we did this without separators we once purchased they are good for the secure than filling the sections (which the secure than filling the s

I was prejudiced in their favor." I am well aware that many will say in regard to my statements about foundation, that" they are no credit to me," as they that "they are no credit to me," as they did in regard to a previous article from my pen on the subject of "comb foundation." Nevertheless, if I say anything about what we use, I must say what I believe to be the truth about it, whether it is, or is not, a credit to me.

Borodino, N. Y., April 5, 1881.

For the American Bee Journal.

# How to Separate Swarms.

Under the above caption Bray & Seacord attempt, in the issue of the Bee Journal of April 6th, to tell how they perform the operation; but after read-ing, the "inquirer after truth" will not

ing, the "inquirer after truth will not be much wiser than before.

They say: "Make a box 3 feet long (or any size that will fit the frames of your hive), make one entrance to the box for the bees to pass in and out; make a tight cover to fit the box, with a last a possible of the same of the or 4 division boards; then the box, will cleats on 2 sides, no end cleats; make 3 or 4 division boards; then the box is ready for hiving the bees.
"Now take the box and hive the cluster

the bees are in the box and mye the chaster of 2 or more swarms, and as soon as all the bees are in the box, put it in a shady place, and let it remain there until the next morning; then push the box cover lengthwise of the box and you will observe each queen with her colony what the swarms are supported by the standard or the standard by the standard or the stand clustered by themselves; now place the division board between each cluster,

the division board between each cluster, push the cover back again over the cluster and hive at pleasure."

Two of the most important points in the operation are left entirely in the dark. What use is made of the frames mentioned in the tirst paragraph, and how are 2 or 3 swarms in one box to be shaken in front of the hives they are designed to eccuy without risking the designed to occupy without risking the original confusiou? When a correspondent attempts to teach others how to perform some original operation, he should be particular to mention every minutia. One omission in this respect will frequently befog the whole business. Kansas, April 17, 1881.

[We observed the omission on the part of the author at the time of its publication, but refrained from calling attention to it for the reason that writers usually prefer explaining their methods in their own way. We are glad, however, that it has awakened criticism, as it forcibly illustrates to contributors the necessity for precision in describing new discoveries. Accuracy should be observed in every detail, and brevity in style of composition.—Ep.]

For the American Bee Journal.

# Ventilation for Winter.

s. goodrich.

All bee men talk about ventilation: All bee men talk about ventilation; the question is, how much is wanted? The novice is inclined to think, after reading about chaff hives and cellar wintering, that his bees must be kept warm, at least they must not be exposed to the winter blasts, consequently he bundles up his bees in a tight-titting hive, covers them with chaff, straw and blankets stops up the entrance so that Inve, covers them with chaff, straw and blankets, stops up the entrance so that not more than two bees can pass, "Now," he says to himself, "my bees are in good shape for any weather." I think blankets, chaff and straw, or any other absorbent, is all right as far as it goes; but bees, like all living animals or beings, require a constant supply of fresh air and a chance for the foul air to escape. Now, I would like to know escape. Now, I would like to know how this is to be accomplished with a

turb or rap them up under any circumstances when it is too cold for them to stances when it is too cold for them to fly. Put your bees in winter quarters before cold weather—before they are done flying—and when cold weather comes on they will go quietly to their cluster, and instinct teaches them the balance; but if you shut them up in an air-tight hive, with no other ventilation than a "key-hole" at the bottom, and stir them up every few days to "roll call" or to hear them buzz, you may expect disease, dysentery and death.

Urbana, Ill., April 8, 1881.

For the American Bee Journal

# Candying of Honey a Test of Purity.

W. J. WILLARD.

The candying of extracted honey is a subject of vital importance to all beekeepers in this vicinity and southward.

My attention has been called to this many times by assertions that nothing but pure honey will candy, and the more so by the resolutions of the Northeastern Bee-Keepers' Association making candying the test of purity. This is a wrong to all of ns (I am no shipper of honey but there are many south of of honey but there are many south of here who are), our honey will not eandy solid, only a little in the bottom when it is taken from certain flowers (and they are the red clover and some of the

For nearly 14 years I have tried to get my honey to candy as I have seen it in the North, but without success. I have exposed it to 16½ below zero in the light and in the dark, I have exposed it to 100½ above in the shade, at the same time had a jar standing in the sunshine where the mereury stood at 128½; none of it candied. This is not the result of one, but of many experiments, therefore I say that the assertion that nothing but pure honey will candy is injurious to many bee-keepers of this county. Nevertheless, I will go heart and soul against the adulteration, not only of honey but of every other For nearly 14 years I have tried to

heart and soil against the adulteration, not only of honey but of every other article of food produced in the world.

Last July (about the middle) when our second crop of white and red clover was just in its prime, I extracted about 12 lbs, of a nearly white honey, put it in quart jars, exposed it to the cold, part in the light, part in the dark, mercury went as low as 16°; up to date there is but about 2 inches of candy in the jars, and that is the nearest I ever knew the and that is the nearest I ever knew the honey in this climate to come to candying, and I have some now which I have

had for 3 years; kept it for experiment. Let our motto be. Down with Adulteration of every kind," but do not fix a standard of purity for honey outside of a chemical test, or you will wrong many bee-keepers who cannot afford the loss which would accrue from the "candy standard.

Jonesboro, Ill., March 17, 1881.

For the American Bee Journal

# Some Incorrect Statements Criticized.

C. A. HATCH.

Several articles from E. A. Morgan, of this State, have appeared in the Bee Journal and should not go unnoticed for fear that some novice might think for rear that some novice might think his remarkable results are easy to ob-tain. He asserts that "basswood buds are all right," etc. We would be only too glad to know that all of this is true, but we have had 4 years experience with bees and basswood trees and we with bees and basswood trees and we cannot tell by what means he can know thus early. Does he forget that even the twig which is to support the flower stalks yet has to grow from the bud? Or, are his eyes so much sharper that he can look down into the bud and see the embryo twig, and even discover the sap which is to develop into the future sap which is to develop into the future bloom? Might he not as well look into a kernel of eorn to determine how many ears the stalk to grow from it will have on it? Is it not a little absurd to talk of the buds swelling when in the same chapter he tells us that the mercury has not been above 30- above zero, and down to 40° below?

He says; "I have kept such in 2-story Langstroth hives and they filled them with bees from June until frost." A with bees from June until frost." A standard Langstroth hive of 10 frames will hold 2,755 enbic inches, and taking ont 10 frames t inch thick leaves 1,412 cubic inches for bee space. One peck contains 532½ cubic inches, and 3 pecks 1,597½ cubic inches. Now when frost comes and he takes off the top story to fit up for winter how could be get 1,597½ cubic inches of bees into 1,412 cubic inches of space?

Let us look at that enormous yield of comb honey. My apiary of 54 colonies has an average of 154 lbs. of extracted honey and but 12 increase. He is not 100 miles away and yet he reports such

honey and but 12 increase. He is not 100 miles away and yet he reports such unheard of yields of honey. Hear him, "my best colony gave me 245 lbs. comb honey, while the parent hive gave 185 lbs." This, according to the custom of counting it all as the product of the original hive, would give 438 lbs. from one colony, and a poor clover yield at that! Did he not measure his honey in the same peck that measured the bees? bees?

Our bees have not been out of the cellar since early in November, hence are getting quite uneasy. It is hard as yet telling what the losses will be; some have lost all, others 12. I have lost 3 vet telling what the losses will be; some have lost all, others  $^{1}_{2}$ . I have lost 3 out of 4 packed in straw out-of-doors, and only 3 out of 54 in the cellar. I have 8 buried in a pit, and do not, of course, know how they are. I have always had best success in the cellar.

Ithaca, Wis., March 12, 1881.

For the American Bee Jeurnal.

## To the Bee-Keepers of Indiana.

L. R. JACKSON.

It would seem from the reports through the BEE JOURNAL that we have lost more bees during the past winter than any other section of the country. This is an evidence that we are behind other States in scientific bee-keeping. We should not allow this to be so. Our State is as good a field for bee-keeping as the adjoining States, and, in some respects, far better. It has not been as well worked in and the and, in some respects, far better. It has not been as well worked up and the as not been as went worked up and the apparist has a better chance to make a selection of a location. Bee-keeping is no longer a business of doubt. We have many bee-keepers all over this country who are making bee-keeping pay as well as any other industry, according to the labor and equital invested and to the labor and capital invested, and far better than many trades or occupations where far more capital is re-

Whatever business we follow we must learn it if we wish to be successful. should learn from every available source. I know of no business that we have as good opportunities to learn from the experience of others as bee-keeping. A scientific bee-keeper is ever ready and willing to assist you; he will give any information that will make you more successful in your business, and will not ask that you pay him a large sum of money for some receipt for taming or handling bees. There is a fascination about bee-keeping that would seem to bind us closely together as members of one family or traternity.

We should take and study the bee periodicals and at least one good book on apiculture. I would recommend Prof. Cook's "Manual;" it is a very scientific work and has done more to aid me in my work with the bees than any work I have read. Such study will improve the mind and make us more useful to ourselves and others. It we take the Journal we get the advice of the very best bee-keepers in the country and have the help of hundreds of intelligent apiarists; each week we receive something new to aid us.

Bee-keeping is yet in its infancy. It has been but a few years since we used the old box hive and knew but little of the interior workings of the hive. Within a quarter of a century there has been more learned about the honey bee than there has in a thousand years be-fore. While many sections of the country are availing themselves of the ben-efit of this knowledge and reaping large Again, those 3 peck swarms, and over—we should eall one peck a good swarm, and any overthat extraordinary. The swarm and any overthat extraordinary.

have ever done. We have every indi-cation of a good honey year. Prepare for it now and have your hives and everything ready in time.

I have no doubt that the past winter has discouraged many who should rather have learned a lesson by it. This rather have learned a lesson by it. This has not been a hard winter on bees in this section of the country, where they were properly protected. I have not had bees winter as well in 5 years as they have this winter, and never have had bees in as good condition the 1st of April as they are now. Bees should be prepared for winter before cold weather sets in. I never allow Oct. 25 to pass without having my bees packed in chaff and all preparations made for winter. I winter on the summer stands, and would winter no other way. I have and would winter no other way. I have never lost a colony of bees in wintering. and will give my plan for packing. I use the Gallup frame, 12 to the hive. In October 1 remove 4 frames and put a chaff cushion on each side, then spread chair cushion on each side, then spread a quilt over the tops of the frames and fill the top story 6 inches deep with loose chaff. If this chaff becomes wet at any time raise the top of the hive and stir the chaff up, leaving the top off for half an hourand the chaff will soon dry ont. If I have any colonies that will not cover 8 frames I double them up with some other weak colony. I use a loose bottom board, and every 3 or 4 weeks I raise the front of the hive gently and brush out all the dead bees. cut a hole through the centre of each comb so that the bees can move from one part of the hive to another without having to go around the frame; then they will never starve with plenty of honey in the hive.

honey in the hive.

Do not put off packing the bees till cold weather or they will be almost sure to have the dysentery early in the winter, unless they take a good flight a short time after they are packed. Packing on the outside of the hive will do but little if any good; the bees will not freeze as long as the inside of the hive is kept dry. If they are strong, as they should be, the chaff will generally take up all the moisture. If this moisture is allowed to freeze on the hive it is very apt to chill the bees to death when it begins to thaw. The hive then becomes filled with a cold damp atmosphere, and you know how guick you chill one of these cold damp days.

In conclusion let me urge all to make

In conclusion let me urge all to make an extra effort this year. If your neighbor bee-keepers do not take a bee-paper show them a copy of the JOURNAL and ask them to subscribe for one; and if you have not read a good work on apieulture, do so at once. One colony of bees intelligently managed will make you more clear money than 5 poorly managed.

Allow me to congratulate the editor on the success of the Weekly BEE JOURNAL. I have often wished for a JOURNAL. I have often wished for a Weekly, but did not think anyone could make a success of it. I no longer have any doubt of its success after reading the many excellent articles in the first months of its publication. I do not think it can be beat as a scientific jour-nal. The editorials alone have been worth more to me than the price of the JOURNAL

Fairland, Ind., April 4, 1881.

For the American Bee Journal. The Bee Moth.

I believe many readers of your valuable JOURNAL will read with pleasure a

ble JOUINAL will read with pleasure a simple method for destroying that pest, the bee moth. The following is one which I have used for the past 3 years:

I placed a gallon mustard jar in my apiary in which I put about 4 inches of water sweetened with refuse honey. The first year I caught hundreds, as well as coolling or apple moths; the 2d year I did not get so many, and the last year I caught but few. I think I will soon destroy them all. The vessel must not be too narrow at the neck. The moths only fly at night; the vessel must be taken in in the day or many bees will be lost in it. The moths must be removed every 2 or 3 days, otherwise will be lost in it. The moths must be removed every 2 or 3 days, otherwise those which come into it will light on

# CONVENTION

## Southwestern Iowa.

The Southwestern Iowa Bee Association met at the Court House in Corning, April 2, 1881.

The President delivered a short but

interesting lecture.

Seven new names were enrolled, making 65 members.

The Secretary read a paper from J.T.

Fife on the management of bees.

L. E. Mercer, Vice President for Taylor county, had the hive formerly adopted by the Association on exhibition, and gave a very interesting description of it; also samples of comb foundation.

of it; also samples of comb formulation, queen eages, prize boxes, smokers, etc.

Deferred subjects for discussion were called up. The purity of drones from hybrid queens was discussed. It was maintained that the drone inherited the purity of the mother, and was not affected by her parties.

G. W. Churchill claimed that by the improved methods of dividing, 2 swarms could be saved in the time lost by the natural or old system.

The following questions were submit-

ted for discussion at the next meeting:
What is the best method of controll-

ing the swarming fever?
Which are preferable, top or side

boxes?
Which is most profitable (the market price being proportionate), comb or extracted honey?

The President named G. W. Churchill, of Essex, Vice President for Page

The Association adjourned to meet at the Court House in Corning, April 30, at 9 a. m. J. T. Fife, Pres. G. W. CHURCHILL, Sec. pro tem.

# Central Kentucky.

The Central Kentucky Bee-Keepers' Annual Convention met at Winehester, Ky., April 5, 1881, Vice President John W. Bean in the chair.

After some preliminary business, and owing to the small attendance (probably on account of the severe weather), the Convention adjourned to meet in the Convention adjourned to meet in Louisville, Ky., in conjunction with the State Convention, which meets in the Exposition Building, Oct. 12, 1881.

JOHN W. BEAN, Vice Pres.

W. WILIJAMSON, Sec.

The Southwestern Wisconsin Bee-Keepers' Association will meet at the residence of W. B. Wallis, at Darlington, Wednesday, May II, I881, at 10 a.m.

There will be an opportunity given for questions and answers. Interesting papers will be read, among which may be mentioned: Location of Apiary, by E. France. Implements of the Apiary, by R. D. Wilson. Feeding Extracted Honey to Produce Comb Honey, by Dr. C. Abraham. Foundation, and its Advantages, by D. R.Sylvester. Bee Forage, by H. Gilmore. Preparation for Winter, by George Fox. Wintering Bees, by Reese Powell. Advantage in Preparing Papers, by E. France. Profitable Bee-Keeping, by E. Pike. The Prize Essay of the N. E. Convention, on How to make the Apiary the most Proditable, by George W. House, of Fayetteville, N. Y. A cordial invitation is given to all. N. E. France, Platteville, Wis.

Programme of the Northwestern Bee-Keepers' Union, to be held at Hastings, Minn., May 17, 1881:

—Address of Welcome, by J. N. Searls.

—Reports of committees.

—Reports from all—number, kind and condition

2.—Reports from all—number, kind and condition of bees.

4.—A paper by Pres. A. Tidball, on honey-producing plants and flowers.

5.—A paper by Dr. Barton, of St. Paul, on honey as food and medicine.

6.—A piary culture and our fairs, by Hon. William Avery, of St. Croix Falls, Wis.

7.—A paper on sales of honey, by F. B. Dorothy, of Taylor's Edls, Minn.

8.—A paper on wintering bees, by L. Day, of Farmington.

9.—Progressive bee-culture, by J. G. Teter.

The above subjects will be open for discussion. In addition to the above, the following subjects are suggested:

1.—Essential properties of a good bee hive.

ted:
-Essential properties of a good bee hive.
-How to prevent and care foul brood.
-How to prevent spring dwindling.
-Comb Foundation, with dividing and natural arming.

swarming.

Appointment of committees.

Election of officers. Adjournment.

All hee keepers are cordially invited. Entertainment free.

F. B. DOROTHY, Sec.

## THOMAS C. NEWMAN.

EDITOR AND PROPRIETOR.

CHICAGO, ILL., APRIL 20, 1881.

## Mr. Frank Benton's Javan Mission.

The following letters from Mr. Frank Benton to Mr. Jones, will be read with interest:

Batavia, Java, Feb. 14, 1881. Batavia, Java, Feb. 14, ISSI.

Dear Mr. Jones:—I arrived here with the bees all right, though some colonies are weak. I will try to save them all. I have, after much work, finally got on the right track and on the right side of some of these Dutch officials, and fully expect to sell the lot of hives—as many as I can put in order off hives—as many as I can put in order—at £5 each. I thought Ceylon a pretty hard place to accomplish anything in—much harder than Cyprus or Palestine; but it is a war a given pretty in this. but it is "not a circumstance to this. but it is "not a circumstance" to this. There are no interpreters here; no natives can speak English, German or French, and only those who have fine government positions can speak Dutch. Having gotten hold of some good men now, I think I will obtain help to secure wild bees, but since they have, every one of them, to be gotten from the forests—to be hunted up yet, and then secured. I do not believe I can get a large number; but I think I shall not meet with losses on the return. Benton.

Beutenyorg, Java, Feb. 15, I881 FRIEND JONES: - I scribbled this note yesterday with a pencil, but came away without mailing it in Batavia. The matter of selling the bees is more certain now. I brought them a day or ertain now. I brought them a day or two ago to this place by rail, and am fixing them up as best I can, and as soon as the sale is completed will remove them to the Government Agricultural School, which is near the hotel where I am stopping. The queens are all right, but in some hives there are but a handful of bees, and in the strongest only 3 combs. They are brood rearing and I shall keep it up by feeding all they will take, and equalizing brood; then I will leave instructions about continued feeding. The government wants to make a thorough test of the matter of make a thorough test of the matter of introducing Europern bees here. The bees Mr. Rykens took from Europe, 24 colonies, nearly all died before he reached Port Said. Five colonies in condition arrived here and lied. Mr. Rykens is now in weak have since died. Europe sick, but they expect him to re-

turn sometime.

The head of the Government Department of Agriculture has instructed one of the officers of the Government Agricultural School to furnish me aid dorsala. So as soon as I have gotten the colonies I brought, in fair condition. I will start out after them. Thave not yet seen a bee of this race, but have seen two combs of these bees, which are 3 feet by 3½ feet, and are 1½ inch thick where brood was reared, about 20 thick where brood was reared, about 20 cells to the square inch; the bees must be  ${}^{7}8$  of an inch long. The combs are never built horizontally—could not be, but are perpendicularly placed on the branches of the trees. The natives get the honey and wax from them, although I was told this morning, by a gentleman who has lived here for 50 cms. that they "sting fearfully;" of gentleman who has lived here to years, that they "sting fearfully; course too much dependence must not be placed upon such a statement. Many who are not bee-keepers would say the same of our honey bees.

I cannot now tell how much money 1

will have when I get back to Cyprus, for I do not know what I must pay out yet; the very cheapest management I can adopt is still costly. Every move made by an American or European costs "like sixty" here. There is no the money must be "forked"

which should meet me there for Ceylon. which should meet me there for Ceylon. I have promised to arrange the bees I have left there, some colonies of which are now in Point de Galle, and for which I was to be paid upon their delivery in Colombo. I expect to get colonies of Apis dorsate there, now that I have been early approach the parties are set of the parties. onnes of Apps torsate there, now that I have learned more of the matter and know where they are actually plentiful. From Ceylon I will sail about March 27, arriving in Port Said about April B; then to Cyprus as soon as possible thereafter, where I expect to receive further instructions as to future operations. instructions as to future operations. FRANK BENTON.

## What Causes Dysentery?

In cleaning out some hives where the bees have died, my observations have confirmed me in the opinion I formed last summer, which is that dysentery caused by starvation. I suppose that many will laugh, but that makes no dif-ference; I look at the reasons they give for their opinions and not their opinions, and hope others will do the same by me. Last summer I divided my bees as usual when there came on a rain that lasted some time; there was no getting honey outside of the hive, yet it was not cold enough to prevent their coming out. I noticed that the hives in which I had placed my new swarms were several of them being spotted up the same as they are sometimes when bees come out in winter. I knew something was wrong. I examined, and found every one that showed signs of dysentery were entirely destitute of honey, and one was much reduced in numbers by starvation. I put in frames of honey, and all recovered and became good colonies. Now Now what but starvation could have produced dysentery in these bives? They had no long confinement, no little poison particles in the honey, for they had no honey had not been eating an excess of old pollen, for the combs were full of brood except the upper corners, where bees seldom deposit pollen. From this observation I conclude that starvation will produce dysentery.

Is that all the cause? Perhaps not. But I must say that I never saw or heard of a case that I could not account for in that way. But, some will say, my bees have the dysentery with plenty of honey in the hive. It is well known that in cold weather bees are very stupid, and those on the outside of the bunch nearly lifeless. Open the hive in cold weather and those on the outer edge of the clusand those on the outer edge of the ens-ter will only stick up their hind end at you, while those inside come out lively to defend their home. It is my opinion that these stupid bees in long confinement starve, and before they die erawl over the frames and discharge their feces. It will be noticed that bees that starve have the abdomen always full of

dysentery feces.
1 have lost 53 colonies out of 113 that I have lost 53 colonies on or 110 that I packed up last fall. All died of hunger. When I pack my bees in the fall I intend to put in honey enough to last them until the warm days in March, and them until the warm mays in March, and no more. I do this because they have less room to keep warm, and I think they are less apt to breed when they have a small amount of honey. I expeet to look over my bees in January or February and give them more honey if they need it, and for that purpose I laid away nearly 300 frames of honey; but I had no chance to examine till in March when they were dead. The live ones I gave more honey, and I think they are all right now.
I might say something complimentary

to the Weekly Ber Journal, but "the rose that all are praising" needs no

praise from me.

E. B. Southwick.

Mendon, Mich., April 7, 1881.

We have published scores of letters stating bees had died with dysentery when there was plenty of honey in the hive; other letters state the bees had dysentery badly, but they enjoyed a purifying flight, and are now quiet and

4, for Singapore, and take the steamer 3 or 4 weeks after a flight, provided the weather be extremely cold or changeable, as 4 or 5 months after a flight? During ordinary winters, when flights are more frequent, although stores are proportionately no larger, dysentery is not of such frequent occurrence as during protracted cold weather, when frost is more accessible to the bees. Again, we have known bees to become bloated with their feces in summer, after several days' confinement, when in transit over rough roads, then standing 2 or 3 days in the shade before being released for a flight; and this with plenty of honey in flight; and this with plenty of honey in the hive. We have opened many cages first I did not like the change from the in which queens and bees had been imported from Italy, to find them all dead, not one-fourth of the honey consumed. but all covered with stinking excrement. They may have starved, but only after having rendered their food untit to be consumed.

> The case cited in the first paragraph of the above communication, is rather a disproof of the Doctor's argument: He divided his bees as usual, the excitement incident to division caused them to consume their stores and become gorged, raining weather set in to prevent timely and necessary flight, and a first-class case of dysentery was rapidly developed as a result. We are sorry to disagree with Dr. Southwick in his conclusions, but cannot indorse his belief.

## Foul Brood.

In the JOURNAL for March 30, page 102, Dr. Wilson ealls attention to Mr. Jeffrey's article on "Foul Brood," because it so fully expresses his views on the subject. I know the Dr. is fully competent to express his views, and I wish he would do so and tell us what he knows on the subject and say whether he considers the disease con-

tagious or not.
On page 68 of the American Bee On page 68 of the AMERICAN BEE JOURNAL, same date as above, Dr. W. says on the same subject: "but for 10 years this (Mr. Jeffrey's belief) has been my opinion,"...." but I refrained from writing my sentiments because all who wrote about it seemed to think that foul brood was a disease to which bees were subject," etc. I am sorry that Dr. W. has not accepted his own advice as given in the last words of his article and given his sentiments in refrainced from the service of the service control of the subject of the service of the service control of the service of the ser advice as given in the last words of his article and given his sentiments in regard to foul brood years ago, and I earnestly hope that he will respond to the editor's request to "let us have the facts and experiences." I have no foul brood among my own bees, but have the care of some colonies that have it, and every apiary in this region that I have examined has what according to and every apary in this region that I have examined has what, according to the descriptions given by our best authorities, is called foul brood, but if Dr. W's, belief "that it is not contagions" is correct, then what we have here is not foul brood, and if they (Mr. Jeffrey and Dr. Wilson) are sight to the first and Dr. Wilson) are right as to its cause, I believe he is right in saying that it is not contagious. I have been keeping some bees in my cellar the past winter for other parties, and some of them have this same disease, and it has not come—from chilled brood either, for the disease is in the centre of the brood nest, and the colonies have been in a

Hest, and the colonies have been in a temperature of about 45° all winter.

I gave a brief description of the disease we have here, in the AMERICAN BEE JOURNAL last July, and before 1 received the JOURNAL that had my ar ticle in 1 received a letter from Col. Whiting, of East Saginaw, Mich., who had seen my description, stating that what I had described was foul brood, and he euclosed a postal card that he had received from a Mr. Walker, giving his method of cure. I have mislaid costs "like sixty" here. There is no choice, the money must be "forked over" or nothing can be done; they bleed everybody who comes, else he goes away without having accomplished anything. I hope to leave here March is not choice, the money must be "forked contented, while two letters speak of improvising house-flights, and thereby checking the malady. If the trouble arise to cure his colonies, and he writes Col. W., "I am happy to say that it has proved a complete success."

I am glad that this disease is attracting so much attention for it is certainly a terrible thing in the apiary. A neighbor who had expected great things from a good sized apiary last season, found the disease so bad in his colonies that he has given up all hopes of doing anything with them, and did not prepare them for winter as he had been accustomed to do.

I certainly hope that Mr. J. and those that think as he does in regard to the cause of the disease are right, and that it is not contagions, but I am very strongly of the opinion that they are mistaken. Certainly the disease we have here is not caused by the brood being chilled, and it is contagious.

Monthly American Bee Journal to Monthly American Bee Journal to a Weekly, but I like it better and bet-ter, and look for its weekly visits as anxiously as I do for my daily paper, and would as willingly do without the anxiously as 1 to 10r my carry paper, and would as willingly do without the latter as I would without the Weekly American Bee Journal, especially if it keeps on improving as rapidly as it if it keeps on improving as raparahas since it changed to a Weekly.

BEE.

It is certainly gratifying to observe the interest being awakened on the subject of foul brood, among those who are perhaps as well qualified to solve the difficult problem as any. That there are conflicting opinions regarding it is not a matter of surprise, when we take into consideration that locality and circumstances may develop contagions and epidemics differently, and frequently confuse scientists into the belief that different disorders are identical; perhaps initial symptoms which at times would result only in epidemies, might under other influences develop calamitous contagions. Hence Mr. Betsinger, when he says "Plenty of honey, no foul brood-no honey, then foul brood," may be right, while Mr. Muth, after years of scientific investigation may also have cerrectly pronounced it contagious, and Mr. Jeffrey, through his interesting observations, may have arrived at no less correct conclusions in attributing gation will not cease till a complete knowledge of its cause, course and cure is obtained, and will second any efforts with this end in view.

Mr. R. M. Argo, Lowell, Ky., writes as follows concerning his experience with the BEE JOURNAL as an advertising medium: "My small advertisement in the Weekly BEE JOURNAL has done me more good than any advertisement I ever put in any paper. I have already sold all the bees I have to spare." Those who have anything to sell should use the BEE JOURNAL for advertising, if they wish to do much business. The large circulation of the Weekly gives advertisers an advantage they can get nowhere else.

Our attention has been called to the fact that we failed to state in the BEE JOURNAL that the Van Deusen flat-bottomed and wired comb foundation received the 1st and 2d prizes in class 25 at the Royal Agricultural Society's Show in London, last July.

FIt is no doubt a great advantage in Germany that practically one size of frame is adopted by all bee-keepers in all parts of that country.

## GLEANINGS.

Peet Queen Cage.-Novice gives the following description of this eage, which is illustrated on the first page of this BEE JOURNAL:

The cage is about 2½ x4½ inches. The side pieces are made of strips 7-32x9-16. The side pieces are each 4½ inches long. The end pieces are each 2½ long by ½ inch thick; this brings the thickness of the ends 1-16 less than the sides, to let the tinglide run over the ends. ness of the ends I-16 less than the sides, to let the tin slide run over the ends. The end piece that holds the candy is made from a piece  $^{1}_{2}\text{xII}_{2}$ ; but before nailing the box together a place is sawed out to receive the candy, so only about  $^{1}_{8}$  of an inch of wood is left on the bottom and end. With a very line saw grooves are made for the tin slide to run in; this slide is bent as shown, for convenience in withdrawing. A corner is clipped from the other end, that the cage may be opened so that one that the eage may be opened so that one bee can be put in at a time, when caging the bees and queen.

The tin points are for fastening the age securely into the comb. Directions for doing this are pasted on the cover of the cage, seen in the foreground. These are simply pieces of basswood, of the cage, one of which has the grain of the wood running crosswigs to prevent the liability of days are has the grain of the wood running cross-wise, to prevent the liability of damage in the mails. The other little board we drop on our grooving saws, to cut the ventilating holes shown in the picture. When ready to nail the tin points are turned down, the little boards placed on each side, and the whole wrapped in strong flour-sack paper, after which an opening is cut of the right over the venstrong flour-sack paper, after which an opening is entor torn right over the ventilating slots. It will be observed we have no bottle of water in this cage. The reason is, that friend Viallon's candy seems to hold moisture enough without it. We will give the recipe for this candy again, as it may not be familiar to some of our new readers.

Take 12 ounces of powdered white igar, 4 ounces of Louisiana brown sugar, 4 onnees of Louisiana brown sugar, one table-spoonful of flour, and 2 table-spoonfuls of honey, stir well together and add just enough water to make it like thick mush; then bring it to a boiling point, or if too much is added boil it a minute or two; then stir it well until it begins to thicken, and pour quickly a table-spoonful into each cage. each cage.

The peculiarity of this candy is that it never dries but remains soft and pasty, but yet not enough so to daub the bee.

## MISCELLANEOUS.

The London Journal of Horticulture makes the following allusion to the Weekly BEE JOURNAL:

The AMERICAN BEE JOURNAL after a well-deserved successful run of 20 years passes into its 17th volume as a Weekly, in which form several numbers between the control of the Weekly, in which form several numbers have appeared. It occupies thus a unique position, which its acknowledged merit will, we hope and believe, enable it to sustain with increasing advantage to itself and the bee-keeping world generally. Several of its correspondents are men of marked ability, while its excellent editor, Mr. T. G. Newman, needs neither introduction nor commendation, since he was with us during mendation, since he was with us during a portion of last summer.

Ammonia, saleratus water, and other alkaline washes are the usual other alkaline washes are the usual remedies for bee stings. A fresh to-matto leaf crushed and rubbed on the puncture is recommended as an easy and sovereign cure.

It is estimated by those best qualfifed to judge, that there are about 10,000 bee-keepers in Cauada. Only a small proportion of these are abreast of the times.

# SELECTIONS FROM

Glucosed to Death.-I like the BEE JOURNAL very much, and would have been one colony of bees better off if I had taken it a few months sooner. I had a colony of bees which east a swarm had a colony of bees which east a swarm late in August, and not having much fall honey I fed them grape sugar, and the result was they died with dysentery; if I had been a subscriber to the BEE if I had been a subscriber to the BEE JOURNAL I would have known better than to feed them that stuff. I took the other colony into the kitchen on Feb. 3d, and having warmed them, let them fly there. We had some dirt to clean up, but the bees had a good tlight, then settled on the window and I put them back. They are in fine condition now, with sented broad. Three-fourths of the bees replaced broad. They are in fine condition now, with sealed brood. Three-fourths of the bees in this part of the country are dead, from not being taken care of. I put my bees under a shed, and packed in chaff at the sides and top. Is maple syrup as good to feed in the spring as coffee A sugar to stimulate for early breeding, or do they need anything if they have plenty of honey? My bees are Italians, of which there are but few in this part of the country and they stood the winof the country, and they stood the winter better than the blacks.

R. P. Williams.

Goldsmith, Ind., April 1, 1881.

[If your bees come out in good condition, now have sealed brood, and have plenty of honey, why do you propose to feed at all? We doubt the propriety of building up very strong colonies too early, unless you have plenty of time and are prepared to feed during the bad weather of this month and most of May. If you wish to breed up early to practice dividing before white clover blooms, then a good stimulant is coffee A sugar dissolved quite thin with hot water, and given about a pint a day. If the bees are flying freely, and you know the maple syrup is  $\mathit{pure}$ , it will do to give it; but if you value your bees, do not take any chances on a mixed article, for commercial glucose is not fit to feed anything at any time.-ED.]

Bees All Right.—I have been very much interested in the reports of disas-ter among bees in all parts of the Uni-ted States, and after many months of grave apprehension in regard to the condition of my bees I am now prepared to make my report. To-day I took my bees ont of the cellar and put them on their summer stands, all in good condition except a few colonies that died of starvation. My bees have been in con-finement for 160 days. I have 56 colo-nies with which to commence the season; most of the bee-keepers in this vi-cinity have only empty hives. Notempty have only empty hives. Not-withstanding the many conflicting opinions in regard to wintering bees, I have, after careful observation and many years of experience, come to the conclusion that cellar wintering in this latitude is far ahead of any and all other methods and moreover that sucother methods, and, moreover, that suc cess in cellar wintering consists in thorough upward ventilation. C. H. TEETSHORN.

Cresco, Iowa, April 8, 1881.

Loss 50 Per Cent.—Bees had their 1st flight Feb. 26, when 36 colonies out of 60 were alive, since which 6 more have died. They were on the summer stands in simplicity hives, packed at sides and on top with clover chaff. The hives were in rows, packed between and at the back, and covered with marsh hay, coming to the ground in front. the back, and covered with marsh hay, coming to the ground in front. A few had no honey, but most of them had honey left in the outside combs, which had holes cut through as passages for the bees, but they starved as they were unable to reach the stores from the excessive and continued cold. We have usually laid sticks across the combs under the quits but neglected to do so der the quilts but neglected to do so last fall, and no doubt much of the loss may be attributed to that neglect. I also think some of the colonies that had

not sufficient stores in the fall and were fed in October, bred too late, for when the cold weather commenced they had the cold weather commenced they had brood in all stages. On examination this spring some of the combs have small patches of dead sealed brood in them. Most of the bees in this part of the country are dead; they were generally kept in box hives and unprefected. Success to the BEE JOURNAL.

A. J. HATFIELD.
South Bend, Ind., April 2, 1881.

Only Empty llives Left.—The bees in this locality are nearly all dead. Winter began in November and it is winter yet. I wintered my bees on the summer stands and I have only a pile of empty hives and dead bees left.
Every one heard from yet has the same general complaint: I have lost all my bees.

B. D. SCOTT.

Ovid Centre, N. Y., April 8, 1881.

Astringents.—A friend of mine had 30 colonies of bees last fall—15 had fall honey, and 15 were fed sugar syrup. Those fed on the syrup came through in fair condition, and the others died. He lays the trouble to late fall honey. Do you know of any one who has tried wintering. tering bees by feeding them syrup or candy made by steeping raspberry leaves or blackberry roots and using the tea to melt the sugar for the syrup or to make the candy? Should think that some-thing of the kind would be good to prevent the dysentery. I have 7 colonies in good condition, wintered without loss.

W. C. Jennison.

Natick, Mass., April 8, 1881.

[We do not know that the experiment has ever been tried, and have a doubt about its feasibility. If it was found that these or any other astringents had a medicinal effect on the bees, the danger would arise of running to the other extreme in their use, and we much oftener would kill our bees in ordinary seasons than save them in extraordinary ones.—Ed.]

Winter Protection.—My bees had a flight on Feb. 10th, and they are apparently in good condition. The bees are in Langstroth hives on the summer stands, with thoroughly cured cornectable acceptance of the conditions of the standard of the conditions of the conditio stalks set around each hive, except the front, and tied in the form of field shocks. I tie a cord around the base of the shock, 2 or 3 inches from the ground, and wind several times above the hive until I bring it to a point at the top; by doing this it effectually sheds off the water, which is conducted, by the series water, which is conducted, by the series of leaves overlapping each other, to the ground. I have examined frequently during the wettest weather, and invariably found my hives dry and free from moisture. On top of the cap, in the opening made by tying the stalks above, because his testical startes of the cap, in the opening made by tying the stalks above. opening made by tying the starks above, I crowd in straight straw endwise, letting it project a few inches in front of the hive. This mode of protection gives ample opportunity, in case of snow, to bank up as high as I wish without getting the snowing contact with the hive and the stalks reaching above. without getting the snow in contact with the hive, and the stalks reaching above the snow, insure ample ventilation. I make a practice of banking in this way whenever there is snow sufficient to do so. In case of a thaw, the snow in con-tact with the stalks melts first, leaving a space of a few inches between the snow banking and the stalks, which frequently become entirely dry and brittle before banking and the states, which frequently become entirely dry and brittle before the banking is melted. All I have to do at any time to examine the interior of a hive is to remove the straw placed of a five is to remove the straw placed over the cap, draw the hive gently forward sufficient to remove the cap, examine the bees, return the cap, slide gently back to the former position, replace the straw, put up the board in front, and all is again snug and cosy.

Fredonia, N. Y. U. E. Dodge.

Will Try Again.—Almost all the bees in this vicinity are dead. Those that were packed with chaff did the best. Some left plenty of honey in their hives. We are not ready to give up yet; many will try again. I cannot do without the Weekly BEE JOURNAL. E. M. POMEROY. Granville Mass. April 5 1831.

Granville, Mass., April 5, 1881.

Wintered on Summer Stands.-1 had 22 colonies last fall, wintered on the summer stands, and now have 20. I have no complaints to make.
O. Sou

O. SOUTHGATE. Smithville, N. J., April 8, ISSI.

Changed His Mind, -At first 1 did not like the change from the Monthly to the Weekly, but now I would rather have the Weekly at \$2 than the Monthly tave the Weekiyat \$2 cmar Go. ... at 25 cents a year. Count on me for a Wm. Birmshier. life subscriber. W.M. Burmmer Tracy Creek, N. Y., April 6, 1881.

Losses In-Doors and Out.—I had 77 colonies last fall and lost none till the end of January. The first I lost was in chaff hives on the summer stands. Those in the cellar 1 found in worse condition. I had 36 in the cellar and 41 in chaff hives and in large boxes, their condition being just alike. I have tight bottoms to all my hives. Three in large boxes wintered well. I lost 17, and 10 were so weak that 1 united them with others, leaving just 50 colonies. One man here having 43 last fall, now has 2 very weak ones left. These now has 2 very weak ones left, were well packed in clover chaff. yet quite cold, but my 50 colonies are in good condition, about the same inoors and out. JAMES HARPER. Mason, Mich., April 4, 1881. doors and out.

Bee-Keeping in Southeast Missouri.—As the flowers failed to secrete honey last season bees in southeast Missouri gathered but little honey, and but few young bees were produced, consequently we had only old bees when they went into winter quarters; hence the losses are very heavy. Old settlers here say they never knew such a season of failure in honey production since this part of the country was settled. This is considered a good location for bees for we have a vast amount of bloom in the spring, and in the fall the whole counwe have a vast amount of bloom in the spring, and in the fall the whole country, and especially the woods, is covered with bloom of every hue, till it resembles a garden of flowers. I can sell all the honey I can produce here at 15 to 20 cts. per lb., but the heavy losses of bees is very discouraging. The last season was almost as great a failure in corn as in honey production. But such season was almost as great a failure in corn as in honey production. But such failures will not stop me from trying to raise corn nor honey—they only learn us a lesson in taking care of our bees at the proper time instead of letting them take care of themselves.

Poplar Bluff, Mo. W. N. CRAVEN.

Honey Poison.—In youth I could not eat honey without its giving me colic, etc., and if a bee stung me the swelling and pain were very great. Since 1875 etc., and if a bee stung me the swelling and pain were very great. Since 1875 I have ate honey and am now a regular consumer of it, without any bad results. These remarks are called out by Prof. Cook's article in No. 3, BEE JOURNAL, on poisonous honey. I do not think that the stingless bees would be worth the investment in this country—they would be continually robbed by the native and Italian bees and would be defenseless. The Weekly BEE JOURNAL tive and Tanth bees and would be defenseless. The Weekly BEE JOURNAL was a grand New Year's treat, and I am glad to welcome it to my library every week. Its contents are all noted with care and I wish it never-dying success.

R. M. Osborn. Kane, Ill., Feb. 15, 1881.

Foul Brood.—I have been working with bees since I was a little boy and am now 65 years old, and I think foul brood is only found among bees that are weak, and I do not believe it to be contagious. Late breeding is the cause; the bees cannot keep the brood warm, and foul brood is the result. There is no need of a law against foul brood, and an inspector to ascertain if brood, and an inspector to ascertain it is in a hive; every bee-man should know it, and he can easily cut out the dead brood if he watches it closely, and thus save all trouble.

SAMUEL NOBLET.
Halifax, Pa., March 2, 1881.

Italians Ahead. - I wintered 2 colonies of Italians and one of native bees on the summer stands, protected from the N. E. and N. W. winds by a house. The Italians wintered well but the black colony died. colony died. E. F. I. Skippack, Pa., April 11, 1881.

Straw and Chaff for Wintering.—My brothers and I had 35 colonies last fall in the "Champion" hive; wintered on the summer stands packed in chaff and straw, and lost 5. About 23 of the bees here about are dead. Mr. J. W. Connor who, like myself, reads the Bee Journal, has lost but 2 colonies out of 12. The spring is very backward; there is an inch of ice on the trees and on the earth here to-day; still I think the prospect good for honey in sonthwest Iowa if there are bees enough left to gather it. I like the BEE JOURNAL and Gather it have been been and the Aping. and Cook's "Manual of the Apiary."

S. C. SMITH.

Wheeler's Grove, Iowa, April 8, 1881.

Wintering In Kentucky. - Many bees have perished in this locality. My loss is 10 out of 85; 5 were starved, 3 queenless, one partly frozen, and one bailes drignosis. WM. C. PELHAM. Maysville, Ky., March 31, 1881.

Five Months' Confinement.—I have 25 colonies left out of 100 wintered on the summer stands without protection. I had no surplus during the past 2 years had no surplus during the past 2 years, though the 2 years preceding I had 75 lbs. each season per colony. The increase was moderate. All had the dysentery last winter. More than 15 of dysentery last winter. More than \( \frac{1}{2} \) of all the bees in this vicinity are dead. My bees had no flight for about 5 months, and have been able to fly only months, and more seem a few days this spring.
R. C. Aikin.

Shambaugh, Iowa, April 5, 1881.

Weevils.—I send you several specimens of a bug (2 females and 1 male). I find them on my bee hives and also have found one of them inside on the frames. What are they? Do they harm anything? If they are an enemy of the bee, I am inclined to the opinion they are a formidable one on account of their natural advantages. Shaped and looking like an iron clad; their armor being corrugated I think the missile of the bee would be harmless, and their shape would prevent the bees from carrying them out of the hive.

A. B. McLavy. Bastrop, Tex., March 28, 1881.

[The insects are snout-beetles or weevils, and hence belong to the great family Rhyncophoridæ. These are very beautiful, and as they are new to our collections, I am very thankful for them. Wrapped up in the cotton, they not only came without injury, but were actually alive upon arrival. All weevils, so far as I know, are vegetable-eaters, not only in the image or mature state, but also as grubs, in which condition they have no legs, and so are often called maggots. This latter name is only proper when applied to the larvæ of two-winged flies. So the specimens sent are related to the plum curculio, the pernicious wheat weevil, and to several of our worst borers. They like warmth, and

I shall be very glad to receive such specimens, especially from the South and West, and will give information in regard to them. If put in cotton they come without injury.—A. J. Cook, Agricultural College, Lansing, Mich.]

have probably learned that the bees fur-

nish this desired caloric, and so are

found about the hives!

Hold Your Tongue, -Without inquiry we learn but little. I have carefully perused Prof. Cook's "Manual," a clear and concise treatise it is, and Langstroth's great work—while both recognize the fact that the "business end" of a bee is the great drawback to beginners, and suggest a number of remedies for the alleviation of the stings, yet both equally ignore the fact that man has within himself a sure, absolute and never-failing prevention. Now what is it? It is simply to take the what is it? It is simply to take the tongue between the front teeth and hold it firmly there, while you dissect a bee, wasp or hornet with perfect impunity. Just how much pressure is req.i.ed I cannot say; being of a timid

nature I generally screw 'em up rather tightly. You say "fudge, that's an old nature I generally serve the my association by You say "fudge, that's an old woman's story, I have heard that ever since I was a boy." So have I, and more, I believe it from actual experience to be true. As to the facts that they exist as stated I have no doubt, and entreat no one to believe or disbe and entreat no one to believe or disbe-lieve them; but my question is; what is it a contraction of, the pores, will, psychology, or, or, or something else? If some kind reader of the Monthly JOURNAL will give the why and where-fore to the above question he will greatly oblige one, and I believe many, of its readers. of its readers. C. H. CLINE.

Weatherford, Tex.

Bees and Granes,-I have kept bees 52 years, and have tried all the different theories of bee-keeping. I used frames in the upper story before the Langstroth frame was patented, only mine were heavy and clumsy and rested on what is called the honey board, and there nailed fast. Except in 1 or 2 winters I seldom lost more than 1 or 2; I pack in dry soft-wood sawdust. I have cultivated grapes just as long as I have kept bees, but never perceived any injury from the bees. A wasp, some like a yellow jacket, some years bites them. one year my neighbor having some sweet grapes complained of my bees; I told him to pick a few bunches that were not stung, put them near my hives, and I would pay him 2s. for every grape that the bees punctured. He did so, examined them every day, but not one was punctured and he gave it up. C. L. Young.

Brecksville, O., April 11, 1881.

Care for the Bees.—I kept bees in box hives in Cortland Co., N. Y., for years, and do not remember of losing any in winter. Since I came to Michiany in winter. Since I came to Managery and I have kept bees and last winter one was queenles and died with about 30 lbs, of honey in the bive.

This winter I have lost one colony. I use the cottage hive, and left my bees on the summer stands until Dec. I, when I put them into the cellar; I took them out on March I. One was weak; I took it into a warm room and them a flight, and then placed them in a sheltered place and they seemed happy. I have but few colonies and give them careful attention, such as a do other stock. I feed them warm syrup every day. Nearly 34 of the bees in this locality are dead.

LINUS REED. them careful attention, such as I

Howell, Mich., April 2, 1881.

Lost All .- I put into winter quarters 43 strong colonies, having young bees and plenty of honey; all in a prosperous condition. I was quite proud of them, and expected by this time to realize a fair income from them, but, alas for "blasted hopes," they are all dead but 4, which are in poor condition. They were packed in chaff on the summer'stands, in the manner recom-mended by Stout Hill, of Mount Heal-thy. They died of dysentery, caused, I mer think, from a poor crop of honey gathered in the fall. The last honey season ered in the fall. The last noney season was poor in this vicinity. My bees worked on the yellow willow about 212 months in the fall; the willow was literally covered with Aphides, and this t think the main cause of dysentery; the honey is very dark and of poor quality I think the JOURNAL is just splendid since it became a Weekly. I prefer it to all others and will do what I can to increase its circulation. Samuel Coulthard.

Preston, O., March 31, 4881.

Chaff Hives .- Four out of 5 of those who had bees here last fall now have only empty hives. Mr. Amos and my-self are more fortunate, ours being in chaff hives. I am trying to get the others to replenish in the spring, and I think they will. I hope we shall have a plentiful season. The BEE JOURNAL is to me invaluable, and I thought last year if it was only a Weekly it would be complete, for a month is too long to wait for the next number. With it and wait for the next number. With it and Gleanings I think I shall be well posted during the coming year.

GEO. E. HILTON.

Fremont Centre, Mich., March 28.

Losses,-I commenced last spring with 2 colonies in box hives; had them transferred into chaff hives; obtained no increase, and only about 30 lbs. of surplus; they are in good order now. I bought 9 colonies in box hives in December, 1880, and packed them in chaff, of which I lost one. I bought 3 more in March, which are all dead.

L. R. Lamb. Penn, Mich., April 9, 1881.

Figwort,---I read the BEE JOURNAL, and am pleased with it. I send you a piece of the stalk, some of the seed bolls and a green leaf of what I suppose is figwort or Simpson honey plant (Scrofularia nodosa. Am I right? I find it on new upland, and it grows as tall as 10 or 12 feet. I would like very much for you to name two or three of what you onsider the best-plants to cultivate for honey; in other words, what is your idea on this subject? V. C. STIERS.
Haydenville, O., April 5, 1881.

[You are right; it is figwort. We think the time is rapidly approaching when all thoughtful bee-keepers will acknowledge the wisdom of planting for bee-pasturage. Of course, opinion will be divided as to the most desirable kinds to plant, owing to adaptability to climate. For spontaneous growth, we prefer sweet clover, catnip, motherwort, ligwort and giant mignonette. For a cultivated crop, buckwheat, alsike clover or mustard. Other plants will undoubtedly be found profitable and desisirable for special localities, now that public attention is being directed to the

Winter Still Hangs On.—We have had for Monthly Bee Journal, \$1.00 less. week of very severe weather and if it. a week of very severe weather, and if it does not warm up soon I shall lose 40 per cent. of my bees. This is the worst month of any on bees, and I have won-dered if those who reported " bees came ore ont good." the fore part of March, can say so the 1st of May? We are not through the woods till May 15th in this locality. G. M. DOOLITLE. Borodino, N. Y., April 7, 1881.

importance of the subject.—ED.]

Wintered Finely.—Our bees have wintered well. We have 150 colonies that have been out of the cellar a month, and 50 more that have not been out in five months—all doing finely.

T. S. Bull & Son.

Valparaise, Ind., April 9, 1881.

Beginner's Experience.—We have A Beginner's Experience,—We have had a very severe winter and to-day the snow lies to the depth of 6 inches on the level. Bees in this section are nearly all dead. I started last spring with 2 colonies, increased to 8 by natural swarming are all dead now but 3, and 1 do not think there are as many bees as in 2 adoptive host spring. They left as in 2 colonies last spring. They left plenty of stores; some had several frames that were hardly touched. I use Langstroth 8 and 10 frame hives and the bees filled the lower story and I left it all in; some say they would have wintered better if I had taken out a couple of frames of comb and replaced them with empty frames, as they would have had more room to cluster. My hees were packed in straw, but they never had a tlight from November until the last of March. There were a few days that a few would come out but only a few returned. I read all I can find about bee-culture and have taken the JOURNAL since it became a Weekly the JOURNAL SINCE A succession and like it very much.

C. W. FISHER.

Lewis, Iowa, April 8, 1881.

Chaff Triumphant.—Out of 109 colonies of bees owned by 14 persons (mostly farmers) last fall, 42 are now dead. loss is 20 per cent.; occasioned by attempting to save some queens through tempting to save some queens through the winter. Full colonies packed in chaff according to the best approved methods came through in perfect condition, without a purifying flight from Nov. 20 until late in March. I am so well pleased with the Weekly Best Journal, that I think I cannot do without if Bryant, Ill., April 4, 1881.

Rees Suffered Severely. - Bees in this part have suffered severely during the winter and a great many have Mine came out as strong as when I put them in, with broad in the hives. I winter my bees on D. A. Jones' system of wintering.

# Books for Bee-Keepers.

Cook's Minutal of the Aplary. Entirely rewritten, greatly enlarged and elegantly Hastrated, and is fully no with the times on every conceivative subject that interests the aparist. It is not only instructive, but intensely interesting and theroughly practical. The book is a misterly production, and one that no beckeeper, however limited his means, can aftered to do without. Cloth, \$1.25; paper covers, \$1.00, postpaid. Per dozen, by express, cloth, \$12; paper, \$3.50.

Quinby's New Hee-Keeping by L.C. Root.— The author has treated the subject of bee-keeping in a manner that cannot full to interest all. Its syle is plain and foreible, making all its renders sensible of the fact that the author is really the master of the subject. Price, \$1.50.

Novice's A B C of Bee-Culture, by A. l. Root, This embraces "everything pertuining to the care of the honey-bue," and is valuable to beginners and those more advanced. Cloth, \$1.25; paper, \$1.00.

King's Hee-Keepers' Text-Bonk, by A. J King.—This edition is revised and brought down to the present time. Cloth, \$1.00; paper, 75c.

Langstroth on the Hive and Honey Bee This is a standard scientide work. Price, \$2.00.

Blessed Bees, by John Allen.—A romance of nec-keeping tull of practical information and contaguous enthusiasm. Cloth, \$1.00.

Rece-Culture; or Successful Management of the Apiary, by Thomas G. Newman, This pamphlet embraces the following subjects: The Lication of the Apiary—Honey Plants—Queen Rearing—Feeding—Swarming—Dividing—Transtering—Indianizing Introducing Queens—Extracting—Quieting and Handling Bees—The Newest Method of Preparing Honey for Market, etc. It is published in English and German. Price for either edition, 40 cents, postpaid, or \$3.00 per dozen.

Food Adulteration; What we get and should not eat. This book should be in every family, where it ought to create a sentiment against the adulteration of food products, and demand a law to protect consumers against the many health-destroying adulterations offered as food. 200 pages. Paper, 50c.

The Dzierzon Theory ;-presents the funda-cental principles of bee-culture, and furnishes a mental principles of bee-culture, and furnishe condensed statement of the facts and argument; which they are demonstrated. Price, 15 cents.

which they are demonstrated. Price, 15 cents.

Honey, as Food and Medicine, by Thomas G.
Newman,—this is a pamphiet of 24 pages, discoursing
upon the Ancient History of Bernard Honey; the
nature, quality, sources, and press and Honey; the
nature, quality, sources, and press and Honey of the Market; Honey as an article of fond, giving
recipies for making Honey Cakes, Cookies, Puddings,
Foam, Wines, Ac.; and Honey as Medicine, followed
by many useful Recipes. It is intended tor consumers, and should be scattered by thousands all over
the country, and thus assist in creating a demand for
honey. Published in English and German. Price
for either edition, 6c.; per dozen, 50c.

Wintering Bees.—This pamphlet contains all the Prize Essays on this important subject, that were read before the Centennial Bee-Keepera' Association. The Prize-£25 in gold—was awarded to Prof. Cook's Essay, which is given in full. Price, 10c.

The Hive I Use—Being a description of the hive used by G. M. Doulittle. Price, Se.

Extracted Honey; Harvesting, Handling and Murketing.—A 24-page pumphlet, by Ch. & C. P. Dadam, Hamilton, III. This gives in detail the nethods and management adopted in their aplary, contains many good and useful hints, and is well worth the price—15c.

Practical Hints to Bee-Keepers, by Chas. F. Muth. Chromati. Ohio; 32 pages. This pamphlet gives Mr. Muth's views on the management of bees, and embraces several of his essays given at Conventions, etc. It will be read with interest by beginners as well as those more advanced in the science of heeculture. Price, 10c.

Kendall's Horse Hook -Nu book can be more useful to horse owners. It has 35 couravings, illustrating positions of sick boses, and trents all diseases in a plant and comprohensive manner. It has a large number of good recipes, a table of doses, and much other valuable horse information. Paper, 25c.

Chicken Chalera, by A. J. Hill.—A treatise on its cause, symptoms and cure. Price, 25c.

Moore's Universal Assistant contains information on every conceivable subject, as well as recepts for almost everything that could be desired. We doubt if any one could be induced to do without it, after having spen a few hours in looking it through, it contains 100 pages, and 500 engravings. Clott, \$2.50.

Clott, \$2.50.

Ropp's Easy Calculator.—These are handy tables for all kinds of merchandise and interest. It is really a highting calculator, nicely bound, with slate and pocket for papers. In cloth, \$1.00; Morocco, \$1.50. Cheap edition, without slate, 50c.

# My Method of Wintering Bees.

S. VALENTINE.

The great and all-important question that comes to the bee-keepers of to-day is how to carry the bees successfully through the interval from the 1st of Is now to carry the bees successfully through the interval from the 1st of December until honey appears in the spring? With all our noted apiarists, Quinby, Langstroth, Wagner, and others, leaders in apiculture who have uncovered much of the desired gold and made apiculture a pleasant pursuit, there are still dark, shady spots that their wisdom has not brought to sun light, and doubtless to-day there is more gloom hanging over the subject of wintering bees than any other in apiculture. Since the subject of wintering stands first on the list of apiculture, and well deserves the earnest thought, careful study, and accurate experiments of the most practical apiarists, for if we fail to winter our bees and spring finds us without them, we need not bother about their management, forage, or about their management, forage, or any of the modern improvements, and we are almost certain to lose them sooner or later if they are not properly cared for. The honey bees are not like other insects, but are more or less active all through the winter and require more or less food according to the quire more or less food according to the amount of heat they generate, and as they become numb at a temperature below 40°, therefore the temperature must be kept up by the bees at the expense of their stores, and if they are kept where they are exposed to extreme cold they will require the more food.

ing: 1st. A failure in late fall breeding; 2d. Unwholesome food; 3d. Lack of stores; 4th. Regular temperature. The first in importance is a good prolific queen, for if there is an old, worn-out queen, or a poor layer in the hive, the colony will be sure to come out weak in the spring, if not dead. In the early part of September it should be seen to that every hive is supplied with a good prolific queen, and if the hive is crowded with honey so that brood-rearing has been cut short, the lower half of the best comb for that purpose should ing has been cut short, the lower half of the best comb for that purpose should be extracted, to give the queen room, or if breeding has ceased from a failure of honey in the field, they should be fed and brood-rearing kept up if possible until the last of October. But before feeding the apiarist should see that the combs are not partly filled with unwholesome honey, but here some one may ask, what is unwholesome honey, and how shall I know it? Apple cider, peach juice, grape juice and such like are not honey. When the bees have had ample time to seal up their stores, and it still remains scattered all through and it still remains scattered all through the hive unsealed, you can take it for bloat you bees. It will pay you well to extract it and feed A sugar.

If you have to feed for winter store it

should be done in time that the bees can seal it over before cold weather sets in. A good, fair colony should have 25 or 30 lbs. of honey, on as few combs as possible, sealed over half way down and before putting up for winter quarters there should be a passage made through each comb, commencing about the centre and extending 3 inches upward, nearly an inch wide, that part of the bees are not cut off from the main cluster by a sudden fall in the temperature.

Now we come to the disputed ground: How and where can we keep the temperature most suitable for our bees? There has been a great deal said about both out and in-door wintering, with great diversity of opinion. I would like to favor ont-door wintering, for it takes a great deal of labor to remove a large apiary to and from a cellar; I cannot help but praise the bridge that carries me over.

From experience I am satisfied that

in our latitude (39½°) we can winter our bees most successfully in a good cellar. All agree a unitorm lemperature is best and to have uniform temperature in the hive there must be quietness, and for quietness we need darkness and a pure almosphere, and cannot these desired points be best secured in a good cellar?

It needs no argument to prove that darkness can be best attained in a cellar, and by proper ventilation a cellar can be kept with a healthy atmosphere. Poor results have been referred to in cellars standing at the freezing point; eellars standing at the freezing point; but I would consider a cellar that stands at the freezing point too cold and a very poor one. The temperature in my cel-lar stood all through this cold winter at 46- and 47-. It is 1214 feet wide by 26 feet long. It has no window, and is per-fectly call, it is right underwall early fectly dark; it is right underneath our sitting-room and bed-room, and is ven-

and often cause the hive to become foul. In the cellar, if properly arranged, they can be transferred to a clean, sweet hive, or the frames removed, and with hive, or the frames removed, and with a piece of tin 4x6 inches clean all dead bees and filth from the hive, and thus keep it clean and pure, which has a great deal to do with keeping them quiet; while on the summer stands, either from packing or a long spell of cold weather, you may not be able to open the hives for months, and a mass of dead, moldy bees, accumulates right beneath the cluster. I know it is claimed that handling bees in a cellar claimed that handling bees in a cellar is also injurious, that they become excited and gorge themselves with honey. I claim gentle bees can be handled in a cellar without much excitement, and a colony in good wintering condition has very little unsealed honey and the bees cannot so easily gorge themselves. They seem to know all about it, or at least are very careless about looking for honey. They have to be forced before honey. They may they will go for it.

they will go for it.

My bees are princely Albinos, which are very gentle and easily handled. I have overhauled all of them twice, and some of them a third time, while in the cellar. I seldom used any smoke, and did not find any of them get excited and make a great ado about it. I open the hive without any jarring, and allow a moment's time for the advanced guard to retreat, and then handle carefully. and they were nearly as quiet when I closed the hive as when I opened it. About the middle of February, before I had overhauled them the last time, a the decame restless, but after I had closed the hive they became quiet again. One might go into the cellar where there were nearly one hundred, and they would scarcely hear the buzz of a bee. I did not let a hive become foul in the cellar and I am satisfied the bees are in cellar, and I am satisfied the bees are in much better condition than they would

have been had I not kept the hives clean.

Six miles from home I had 15 very strong colonies with plenty of honey which I left on the summer stands. On which I left on the summer stands. On the 10th of February I went to see them, and found one dead with from 30 to 40 lbs. of sealed honey in the hive, and they all had very many dead bees on the bottom-board, some of them smelt badly and had dwindled very much. I have lost one since, and several are in a critical condition.

critical condition.

Last year I bought and started a small apiary of 15 colonies in West Virginia, for experimenting. They did well through the summer. I think it a good locality for honey. Some of them made me from 25 to 40 lbs. of section honey after harvest, and in October, when I saw them last, they were all very strong with bees and had plenty of honey to with bees and had plenty of honey to carry them through, except two, which were badly managed in the early part of the season, and being crowded with work in the fall, I was unable to give them any attention. Now I am in receipt of a letter which states that there are over ½ of them dead.

My home apiary I have been using exclusively for anear, rearing and ship.

exclusively for queen-rearing and ship-ping purposes. Last year we had a very poor season, but 5 weeks of a honey I have been experimenting for some years on wintering bees out and indoors, and I am satisfied that bees will winter best at a temperature about 45°; but from experience we have learned that there are 4 things in the hive that are against successful winter-

idea of the condition of my home apiary for wintering. However, about the 1st of November I doubled up and prepared 76 colonies and 24 nuclei for wintering. 76 colonies and 24 nuclei for wintering. My nuclei were nearly all out of honey but I had some sections 6x6 and some 5½x6 filled and partly filled with red clover honey, I went to work and made nucleus boxes to suit them, some to hold 3 and some 4; I cut a rabbet 2½ inches deep to give ventilation and room to feed candy on top, transferred the bees into them, but the smell of honey excited some to robbing, and I was obliged to take them to the cellar. They seemed to do well for a few days, but in a week or 10 days became restless, and on examining found about ½ of the bees dead. I cleaned the boxes and bees dead. I cleaned the boxes and bored 2 5g holes in the rabbet, one in front and one in the rear, to give venti-lation; but in a few days I found there was not enough ventilation. Oh! how I wished they could have a good flight; but the weather was too cold. I went to work again and made other lids, with an opening in the centre 24x4 inches, and covered it with wire-cloth, cleaned the hives again, and put the new lid on, and in a few days found that those bees that were almost helpless had become dry and bright. I succeeded in carrying 19 of them flrough the winter. I lost 4 by letting them get out of food, and on the little of Edward the work. and on the 12th of February the mer-cury rose to 50°, and I put them out for a flight, and lost one queen by swarm-ing out. In the evening I again re-moved them to the cellar, and gave them some candy, and covered the frames with cloth and they commenced rearring broad rearing brood.

November came in with colder weather than usual and I was waiting with my colonies to give them a good flight before putting them into the cellar; but severe weather set in about the middle of the month and they did

lar; but severe weather set in about the middle of the month and they did not get it. I put the most of them in the cellar in November, but did not put them all in until the last of December. I had lost 4 colonies before I concluded to put them all in. I lost but 2 in the cellar which starved. This leaves me 70. When I overhauled them in February I gave all of them some candy and ixed them up for brood-rearing, and in a week's time they nearly all had commenced brood-rearing.

I leave them in the cellar and stimulate with candy until mild weather and young bees are hatching freely, then I move them to their summer stands, and cushions on the sides with sawdust cushions. I prefer fine dry sawdust for cushions at the side, as it is the best non-conductor, and will keep the bees warnest. But over the top a chaff cushion or anything that is a good absorbent. I think on top is the proper place to take up the moisture. With this method I have been successful and have avoided much spring dwindling. From 1875 to 1879 I wintered in the celtar with a loss of but 4 colonies. Last have avoided much spring dwinding. From 1875 to 1879 I wintered in the cellar with a loss of but 4 colonies. Last winter I wintered with success on the summer stands, and vice versa; but I can assign causes for so doing. We had a very mild winter, and bees could fly nearly every week all through the winter, and my hives had impure honey in them, and I wished to take a trip

section of the country. There has been some excitement on the subject, but the poor bees were generally left on their summoer stands without any protection, and doubtless many of our bee-keeping friends will remember the winter of 1881, as I remember the winter set in very cold. winter of 1881, as I remember the winter of 1886. That winter set in very cold the 26th of December, and continued cold until April, and we had but one colony left in the spring. But one of the best honey seasons followed that cold winter that I ever knew. This winter the loss will far exceed that of 1856, for there were many more bees to lose. I will venture that there will be a loss of 75 per cent. of all the bees throughout these regions.

This winter has been exceedingly cold with us, the temperature often below zero. Several times way down in the teens, and on the 31st of December and 1st of January it ranged through this valley from 22 to 30 below zero; at my office 26. Now, bee-keepers of this latitude you may winter your bees

at my office 26. Now, bee-keepers of this latitude you may winter your bees safely without much care, but you cannot expect every colony that is not in the very best condition to go safely through such a long cold winter like this without some protection and care. Do men leave their horses and cattle exposed to such severity? No; they provide shelter and comfort for them. In the far West where stock is not thus provided for, this present winter has been very destructive on all kinds of live stock. Thousands of cattle have died on the prairies and Western lands. Now, friends in apiculture, who have died on the prairies and Western lands. Now, friends in apiculture, who have lost so heavily, consider well where the fault lies before you give up in disgust and seek some other business that you may think will not be so destructive, and that will pay better.

Double Pipe Creek, Md., March 30.

## For the American Bee Journal Relating to Pedigree in Bees.

WM. F. CLARKE.

It is about time that bee-keepers were seriously considering what steps ought to be taken to render the breeding of improved strains of bees a more "exact science" than it is at present. The multiplication and wide diffusion of untested and cheap queens, while it has no doubt infused a large amount of new no doubt infused a large amount of new vigor into the bee population of this continent, which had become deteriorated by in-and-in breeding, has nevertheless created "confusion worse than confounded" in many cases. Inexperienced bee-keepers who have got watertad event have hard been the computed. untested queens, have hastily concluded, when they saw how different their progeny was from that of the black queens, that all was right; they were genuine that all was right; they were genuine Italians, and no mistake. From their ignorance, and with no intention to mislead, hybrids of all grades have been disseminated under the name of Italians, until they have "harked back" to the common type, and lost every vestige of the golden hue that gave them distinction. Well, the cross was worth its cost which was not much and them distinction. Well, the cross was worth its cost, which was not much, and the common stock of the country is all the better for it.

But to our best bee-keepers—those who are thoroughly intelligent and enwho are thoroughly intelligent and enterprising, that hap-hazard kind of improvement is only the "small drop in a bucket" compared with what they are aiming at, and expect to see realized. They believe that we have only got fairly under weigh—the voyage of discovery is yet to be made. There is reason to think as much improvement can be made in here-breeding as in entitle. be made in bee-breeding as in cattle-breeding, but we are very far yet from having such an advance on the common bee, as the noble short horn is on the scrub race of cattle. Shall we get it: Yes, with the requisite painstaking and

perseverance.

To-day, the chief drawback to average short horn excellence is the persistence of a certain class of breeders in demanding that a specific number of

nres), there will always be some un-certainty as to the absolute purity of stocks bred in the usual way. We don't stocks bred in the usual way. We don't yet know how far queens will fly in search of a mate. Mr. Jones says he yet know how far queens will ly in search of a mate. Mr. Jones says he has "proof of mating many miles away." If that be so it would seem that his plan of isolated islands is the only one that is entirely safe. I never was a friend to monopolies or patents in the bee business, but either Jones has gone to a vast amount of unnecessary expense and trouble to secure infallible purity, or there are a lot of queen-breeders who need shaking out fallible of their boots for carelessness, and a too great readiness to guarantee purity.

too great readiness to guarantee purity. Short as is the time since their introduction, the market is flooded with advertisements of Cyprian and Palestine queens. How many who offer such queens for sale can pedigree their stock? A pedigree to be worth anything must have a double action; backward to purity and forward to purity. There must be no probability or guess-work about it. There must be certainty or we are building on a shaky foundation. we are building on a shaky foundation.

As a contribution toward the discus-

sion of this subject I venture to make the following suggestions:

1. That every imported Cyprian, Palestine, or other choice race of bees, should be certificated as to its history,

should be certificated as to its fistory, shipment and delivery.

2. That queen-breeders should give their customers particulars as to the circumstances under which their stock is bred. There is a sensitiveness about is bred. There is a sensitiveness about guarantees which had better be superguarantees which had better be super-seded by something equivalent to pedi-gree. This is done with cattle and other stock. It is not enough for the seller to say, "I guarantee purity," he furnishes the record. In like manner, a treasurer not merely guarantees his ac-

treasurer not merely guarantees his accounts, he produces vouchers.

3. That every breeder keep a record or register of extra fine strains that develop in the course of his experience. Just as there are families among the short horns, like the Duchess tribe, of superletting are strained. short horns, like the Duchess tribe, of superlative excellence, so, in proportion, is it among bees. Every such strain should be cherished, carefully kept track of, and experimented with, for it is out of the aggregation of these excellent points that the bee of the future is to be evolved.

4. Now that we have at least 3 choice races to experiment with careful record.

races to experiment with, careful record should be made of all crosses. In due should be made of all crosses. In due time the lucky hit will be made that will give us the longest-tongued, most vigorous, and consequently most desir-able bee. When that hit is made we

want to know how to do it again.

5. Will it provoke a smile to propose a public registry of bees, analogous to the "Short Horn" and other herd books? Well, then, as I don't like to be laughed at I will let some one else

make that proposal.

Lest anyone should suspect me of having an axe to grind I will say that I am in no way interested in queen-breeding, except as every bee-keeper ought to be; that is, anxious that all may get the best. I never sold a queen and never expect to. Bee-keeping has al-ways been with me a study and a pas-time, " only that, and nothing more." I have never been in a position to keep with an eye to profit.

# Treatment of Foul Brood.

A. GRIFFES.

Last spring I had one or two colonies affected with foul brood, and thought when they became strong I would start them anew, but one I brimstoned, and age short horn excellence is the persistence of a certain class of breeders in demanding that a specific number of crosses on the original native shall pass for thorough-bred. Yet every well-posted breeder knows that such is the prepotency of the native stock, that the old bad blood will keep showing itself for many generations. It is the same with fowls. A significant feather or a redundant too will tell a deleful story to injust the took 3 more, and in a few days. with fowls. A significant feather or a ers in 2 places on the frames. The next redundant toe will tell a doleful story to night I took 3 more, and in a few days

put 2 more together. That made 3 colonies of 8, and they filled the frames and reared brood in abundance. I fed them up with coffee A sugar to winter on, and there was no sign of foul brood to be seen last fall. There were 2 strong colseen last fail. There were 2 strong cor-onies left; these I put in my cellar and starved for 24 hours, put them in the box just at night, and kept them until the next evening, when I put them in a new next evening, when I put them in a new hive, gave them a comb with about two lbs. of honey, and they went to work with a will on the buckwheat, and no foul brood in either of them. I found one after that, late in the fall, which I brimstoned. Now, I do not kill bees if I can help it. May be some more in the spring spring.

I have 63 colonies in the cellar and doing well, except one that shows dysentery a little. I expect to lose that one because there has been no time they could fly since last November.

Albion, Mich., Feb. 10, 1881.

From the Chicago Times.

# How the Bees have Wintered.

PROF. A. J. COOK.

Each winter at the agricultural college the bees are protected in the several ways advocated in the country, that we may determine after a series of years which is the safest and best. We have which is the safest and best. We have become convinced by our own and others' experience that non-protection is never wise, and so have ceased to experiment in that direction. The same holds true as to the method of burying.

Last autumn we placed ½ our bees in the cellar, the remainder were packed in straw one foot thick on each side of the hive. One of these latter was in a Shuck hive. All those left out and packed had 6 inches of chaff above the bees. Each of all the colonies was given some 25 lbs. of good honey. All were prepared for winter the 10th of Nov., 1880. in straw one foot thick on each side of

Nov., 1880.

Owing to the severe and continued cold the bees were not able to tly from their hives for 5 months. March 10 they could fly, and all were examined. Those in the cellar were all in good condition. Of those out-doors half were dead and the others weak. The one in the Shuck hive was best off. We then put all in the cellar, except those in the Shuck hive, which have since died. The Shuck hive, which have since died. The others are all alive yet, and we feel quite sure we can save all, unless the weather fights it out on this "blizzard"

line all summer.

All through Michigan the same holds true. Bees in good cellars have suf-fered very little. I even know of some that were moved into such cellars as late as the 1st of December that have come as the 1st of Peccember that have come through all right. Those in chaff hives are, so far as I can learn, from \(^1\_3\) to \(^1\_2\) dead, with the tendency strong towards the dead line. Those left improtected are all dead.

Another feature not without interest Another feature not without interest in the matter is the amount of honey consumed. Bees in the cellar have eaten but very little; those out doors have consumed 2 or 3 times as much. Our bees in the cellar have eaten, in every case, less than 10 lbs.; those out doors have in some cases left but very little honey in the hives.

I have no doubt but that the cause of the great mostality is dysentery induced.

the great mortality is dysentery, induced by over-eating and long confinement. Bees, unlike most insects, are not dor-mant in winter, but with the temperaare very quiet and take but very little food. Thus conditioned they will bear continement 6 months with no apparent confinement 6 months with no apparent harm. But if the air becomes much colder than this, or much warmer, especially if long continued, the bees become uneasy, eat more, become distended with the refuse in their food, and unless soon able to fly forth and void their feces are attacked with fatal dysentery. In cold weather this activity, whether of motion or functional, is to supply the heat necessary to preserve life, and the extra activity demands an extra quantity of food. The heat in a warm atmosphere becomes an

bees through any winter safely. It has been done in all the trying winters of the past. Where there has been failure inquiry showed that the bees were in a poor condition in the autumn, or that they had a poor quality of honey, or else the cellar was not so arranged as to-preserve the uniform temperature. The preserve the uniform temperature. The old idea that a cellar must be dry is not wholly correct. I have tried a cellar for the past 2 seasons that had several inches of water in it continually, and with entire success. Such a cellar ought to be well ventilated. Chaff hives usually may do as well as a cellar. But that they will prove as safe as a first-class cellar in very severe winters does not seem to be verified by the past "sea

As probably ½ of the bees in the Northern States are dead, we may well look for a corresponding decrease in the honey production; and with a lessened supply will come an increased demand and high prices. The prospect for an unusual production in California will only partially make up this deficiency.

Lansing, Mich.

For the American Bee Journal.

# Top vs. Side-Storing.

JAMES HEDDON.

years have And hives that were strongly advocated, as exclusively side-storing hives. They were called the "New Idea" hive and were invented by Adair, Gallup & Co. They stored both comb and liquid honey on one side or both sides of the broodnest. All of us who were induced to leave the old standard Langstroth and adout the long hive either wholly or in adopt the long hive, either wholly or in part, soon saw our mistake and returned,

like prodigal sons, to former habits.

Next, I conceived the idea of a com-Next, I conceived the idea of a combination of top and side-storing, and made a dozen or more hives for that purpose (one of which still occupies valuable room about my houses), but soom discarded them as no better than the all-top-storing Langstroth, and more than twice as much labor to manipulate. Now, I do consider the shape of Mr. Doolittle's hive faulty, because I, like him, prefer small hives, which are more easily kept chock full of brood, and which I have never seen occasion to disclaim since I so warmly advocated them.

which I have never seen occasion to dis-claim since I so warmly advocated them, some 6 or 7 years ago at our State Con-vention at Kalamazoo; and if small, they cannot be extremely high unless-very narrow and short—not very long, unless very narrow and shallow. For wintering I prefer fewer ranges of comb-and longer ones, as bees move back and forth with the ranges easily, when they and longer ones, as bees move back and forth with the ranges easily, when they cannot do so across them. The 8-frame Langstroth hive seems to me to be about the happy mean between the extremes. It is narrow enough for wintering, it is shallow enough and has top curfact anough to weak the processity of tering, it is shallow enough and has top surface enough to avoid the necessity of putting boxes at its sides, thus causing the master to place them twice before removing them. Is it not very plain that one man can care for double the number of colonies with my case system that he could do with your method, where the surplusage has to be handled over twice or more before its removal?

Why sidestoring was the original

Why, side-storing was the original plan, before the skillful Langstroth or any other bee-keeper invented open top frames, and no doubt has been used by hundreds of apiarists years ago, both exclusively and in conjunction with the on the popular side of this question, as hundreds to one use and swear by the flat top-storing hives. Still, it might be wrong, but I think not. I bring as evidence the well known fact that the very first wheat the these was the first way in first place that bees use the first wax in the spring is in the top of the hive, between the top bars and cover. If I used a hive that had only about one square foot top surface, and used boxes 6 inches high, I do not know but I should look more kindly toward the complicated system of moving boxes from the wrong place to the right one about the hive, serve me, and the extra activity demands an extra quantity of food. The heat in a warm atmosphere becomes an irritant which produces uneasiness, and, as a consequence, more food.

I believe that with good food and a cellar which will preserve the proper uniform temperature we may bring made the bees take it for young combs, I think that the man who would change to any other arrangement must see something that I cannot.

When the first twenty-four  $4\frac{1}{4}$  sections are  $\frac{2}{3}$  full, or less, if the bees seem anywise crowded, up they go and under goes another case of 21 more, so fixed that the labor is about one-half done to begin with. Note that the labor is a local to the second of the second that the labor is about one-half done to begin with. Now we have 50 lbs. capacity on the hive, and the topmost piece of comb in the whole arrangement is less than 18 inches from the lowest cell in the hive. How much shorter is the distance from cell to cell in Mr. Doolittle's arrangement? If it should happen, as it sometimes does, that more room is needed before the that more room is needed before the first case is all complete, shove under another, or two of them if you choose, and take my word for it, all will go along

and take my word for it, all will go along satisfactorily.

Like Mr. Doolittle, I speak from experience. About 10 years ago I used a 40 lb. box. It was 15 inches square, and about 7 high, and contained topbars. It was used on a bar hive of its own size and 13 inches deep. I tiered up 4 of them on one hive at one time, and both them all for its days that them all for its days and a fifth and had them all finished, and a fifth one nearly half completed when the season closed. I also tier up the 5x6 season closed. I also tier up the 5x6 sections with about 15 colonies out of 100, each tier containing a capacity of 45 lbs., and the system works perfectly here. There may be a difference in lo-calities, but I feel sure that the I lb. sections in the shallow cases will work

sections in the shallow cases will work well tiered up anywhere.

I hardly ever give my "experience" to prove my opinions, as it is so very difficult to prove the experience first, but thinking that perhaps many readers will be as willing to take my word in this controversy as I am that of my esteemed friend Mr. Doolittle, I will further say that I once obtained 410 lbs. of surplus honey from one colony in one ther say that I once obtained 410 lbs. of surplus honey from one colony in one season, 48 of which was extracted from the brood chamber, but 362 of which was comb honey taken upon the tiering up system from the top of one of those 15 inch square hives, 13 inches deep, in boxes about 7 inches high, and not a particle of starter of any kind used at all. Now, reader, if you had met with the same experience with such fixtures as the above described, would you be afraid of the "tiering system" with the modern appliances, as described further back? I agree with Mr. Doolittle, that bees will store honey faster above than at the sides, and I also claim that where at the sides, and I also claim that where they prefer to store nectar they prefer to construct the receptacles to hold it. Above is the heat and odor of the hive, also is it further from the entrane (where envious enemies can come), and, according to Mr. Langstroth, the very place where bees could and would soonest put their surplus combs of honey.

I wish to say to Mr. Doolittle, that when I find a queen that fails to fill my 8 frames reasonably full of brood (outside and over all), I supersede her at once from my best stock.

I have been talked to considerably because I did not use 10 Langstroth frames instead of 8, but I do not care to whip up my cueens at all so long as

frames instead of 8, but 1 do not care to whip up my queens at all, so long as they are normally prolific. Rather cut down the number of frames, because, recollect, the capital lies in the combs and hive, and not in the queen. I have no trouble with clogged brood chambers, because my sections have perfectly free communication with the brood nest, which is flat, and as they are well supplied with that which is comb in 12 to 24 hours at the option of the bees, they leave the cells below for the queen, knowing that she will not want to commence a brood nest in so small sections of comb as 44 inches square. All these of comb as  $4\frac{1}{4}$  inches square. All these points have been thought over and put to test during the past 5 years.

I am aware that different localities am aware that different localities demand different systems of management; also, that these different systems suggest different forms and sizes of hives and other fixtures. Nevertheless, I hope some good may grow out of the earnest and pleasant discussion of all subjects portaining to our favorite pur-

bee disease till the first issue in May next, when I will do so with pleasure. I feel sure of my premises, and of my ability to make them clear to the read-ers of the BEE JOURNAL.

Dowagiac, Mich., April 11, 1881.

For the American Bee Journal.

## Artificial Swarming.

HENRY ALLEY.

Hundreds of bee-keepers will make an effort during the coming season to build up their apiaries destroyed the past winter by the severe cold weather. past winter by the severe com weather. How can the old combs be best utilized and colonies increased in the most economical way? I will give my views on this point as I have had some experience the business. Artificial in this part of the business. Artificial swarming will have to be resorted to for rapid increase of colonies. It should not be attempted too early in the season. Old colonies should not be disturbed until they are full of bees and honey, or, in other words, till they are ready to swarm.

Then if the new colonies are to have the life hew colonics are to have the old combs only a moderate quantity of bees should be taken out and at the proper time a queen gives them. Three quarts of bees will make a fair sized colony. The parent colony should then be left 10 days at least (14 days is much better) before it is disturbed again, for this purpose this can be done as often as every 2 weeks, provided the old colony retains the queen. Do not remove the queen and bees too; artificial swarmthe queen and bees too, artificial swarming in that way would soon ruin the best apiary. If the parent colony is forced to rear queens and bees, too, artificial swarming would not be a success. A good queen is worth \$2 on an occasion like this.

occasion like this.

The reader will readily see that if the bees and queen are removed from a hive the remaining bees will have up-hill work to build up again. What bees remained could not rear a vigorous and strong queen, especially if the old colony is removed from the stand and the new hive put in its place.

If groups are given the new colony 3

If queens are given the new colony, 3 times as many colonies can be made in the course of the season as could be done if the old colony is forced to rear

queens every time.

Artificial swarming can be practiced up to August 10. I would not advise it done later than that date, because the colony would not have time to rear a sufficient quantity of bees to insure safe wintering. Old bees cannot stand the rigors of winter, and in fact their lease of life would run out before spring

opens, in any event.

opens, in any event.

Natural swarming cannot be depended upon for rapid increase. With liberal feeding and supplying the new colonies with queens 5 good strong colonies could be made from one, between June I and Aug. 10. I do not advocate too rapid increase. If forage is not abundant feeding must be resorted to. Do not let the feeding go till too late in the season, trusting the bees to get their living. Commence to feed as soon as the colony is ready for business, and that will be the next day after they are put into the hive. If you would make this whole arrangement successful do all the feeding not later than Sept. 20. A little food might be given later to

all the feeding not later than Sept. 20. A little food might be given later to stimulate breeding. All the syrup given them should be sealed up before cold weather sets in or it would sour before spring, and dysentery might be the result.

My plan for feeding is this: To 6 lbs. of coffee or granulated sugar add 2 qts. of water. Dissolve in hot or cold water. The best feeder for general use is a pint "improved Mason fruit jar." These jars have glass tops. Remove that and substitute a tin one. With a brad-awl make from 4 to 20 holes; for slow feeding make from 4 to 6. When a honey board is used make a hole 1½ inch in diameter and place the jar over it. If feeding at the entrance is desired make

the hives with empty combs; then shake about 3 qts. of bees in front of it. When they have all run in close the entrance with wire cloth. If the hive has a portice nail the wire on front, or beta portice han the wire on front, or out-ter still, have a screen made for the pur-pose. The idea is to give the bees plenty of air. Leave room between the entrance and wire cloth for the bees the entrance and wire cloth for the bees to fly or run about. Keep the bees shut in 36 hours. Keep a wet sponge against the wire screen and they will not suffer for water. If this is done towards night they can be let out the second morning after, and being few will re-turn to the old place, as they will be-come reconciled to the loss of the queen. Let the old hive remain in its place and Let the old hive remain in its place and put the new one 5 or 6 rods away. At the end of 2 or 3 days give the bees a few puffs of tobacco smoke and let the new queen run in. Do not put her near the hive till she is introduced. In the course of 8 days examine the brood given them and if they have any queen cells destroy them. Combs taken from the hives where hees have died with dysentery can be used without danger.

Wenham, Mass., April 5, 1881.

# Rock River Valley,

The Rock River Valley Bee-Keepers Association met in Monroe, Ill., March Association met in Monroe, in., March 29, 1881. Few members being present (owing to the impassable condition of the roads) the forenoon was spent in general consultation concerning the welfare of the bees. At 1 p. m. the Convention was called to order and the following colors were related for the following officers were elected for the

President, A. Rice, Byron; Vice-President, H. Everton, Monroe; Secretary, D. A. Cipperly, Monroe; Treasurer, J. J. Crill, Monroe.

The Treasurer's report was read and approved, Members reported as follows:

approved. Members reported as follows: Number of colonies in the fall 207; number of colonies at above date 44. Two reported surplus: II. Everton, Two reported surplus: II. Everton, 300 lbs.; E. Lucas, 600 lbs.
E. Lucas reported no loss from 38 col-

onies, with plenty of honey and brood.

The cause of bees dying with plenty of stores, both in cellar and on summer stands, was requested to be answered in the American Bee Journal.

[For answer see next page.—ED.]

The President's address is as follows:

## President's Address.

Ladies and Gentlemen: - We meet today at the close of one year's existence of our Association, to discuss questions of interest pertaining to bee-culture

of interest pertaining to bee-culture.

Our meetings have been attended with a good degree of interest, notwithstanding the unfavorable season for bees. Our interests have been one, our actions harmonious—"United we stand, divided we fall." I believe we shall find it not only pleasant but profitable to meet occasionally to impart what we know, be it much or little, about the management of bees. When each of us comes to get, and none to impart our knowledge (which I trust will never be), it would be advisable to indefinitely postpone our meetings.

The different races and grades of bees, the different ways devised to secure the largest income for the smallest outlay.

largest income for the smallest outlay, is what we have all been striving for until it would seem impossible to more than repeat the words that have been spoken many times before; therefore nothing new will be expected of me at

this time.

Of the different races of bees in expected has not had hives and other fixtures. Nevertheless, I hope some good may grow out of the earnest and pleasant discussion of all subjects pertaining to our favorite pursuit.

If am at present much hurried with home labors, besides 6 regular communications promised each month, and I will not be able to reply to Mr. Doolities at the same time proceed thus:

To introduce queens and make new colonies at the same time proceed thus:
From a strong colony take one full comb and place it in the new hive, filling up the first part of the different races of bees in existence there is one that has not had its share of attention, although it has associated itself intimately with the whole human family from our first parents to the present time, and that is the "may be." Did not mother Eve say to her husband, "take and eat of this fruit (although forbidden); may be it will not hurt us. may be it will do us good?"

At the National Convention, at Chicago, we understood from an able beemaster that we might take a colony ever so carefully in our arms from the apiary to the cellar, may be it will die. Take another colony on a barrow, however roughly we handle it, may be it will live. We further understood from the same gentleman that one colony might go South and may be gather healthful honey and live. Another colony go North and may be gather poisonous

honey and die.

Have not most of us had too much to Have not most of us had too much to do with that may be? Do we not too many of us too often say may be the winter will be warm and the bees need no care; maybe it will be as well to pack or cellar the bees in December as November; may be they have honey enough or will gather enough, etc., in ways almost without number? That may be proves fatal to our bees. I will leave the may be, only saying that it is not and never was a scientific bee. Our attention is often called to the differences of opinion about the management of bees. One gentleman at the Convention in Chicago said in wintering bees in the cellar it is of first importance to keep the cellar dark; an-

portance to keep the cellar dark; an-other said that light does not disturb his bees in the cellar, that he does not darken his windows and leaves the door darken his windows and leaves the door open in the daytime, as occasion may require, with no injurious results. We have all noticed that with the shades of evening our bees return to their hives, and go forth to their labor with the light of day, except it is stormy or too cold for them to fly, and I have found bees improving the first opportunity to leave the cellar after opening the door. leave the cellar after opening the door, when the atmosphere was sufficiently warm for them to fly, and I think it would be impossible for us to educate them otherwise.

The relative value of the imported to the home-bred bees has, of late, been somewhat discussed. The resolutions somewhat discussed. The resolutions of the National Convention, at Cincinnati, are as follows:

1. Resolved, That the importation of pure Italian, Cyprian, and Palestine bees into North America ought to be encouraged for the sole purpose of adding new and different strains of blood to that which we already have.

2. That the strains of Italian blood

2. That the strains of Italian blood which we now have has reached a higher

which we now have has reached a higher standard of excellence than is to be found in the native home of the Italian.

3. That queens reared from pure, selected, home-bred Italian mothers, should command at least as high a price as those bred from imported mothers, where pure Italian stock is the sole object desired.

I think the 2d and 3d resolutions are rather in conflict with the 1st, for how can we import and sell at the same price as those that are only bred from home stock? The question for us to decide is, which will we patronize—the price being equal—those who breed from imported or those who breed from home stock? Most of us will always pay the importer the higher price.

The past year has been a failure with bees and honey to nearly all in this vicinity. Very few report any surplus, therefore the question to solve is, what shall we do? Shall we give up the busisnan we give up the business or shall we try more and better care for our bees in winter, spring and summer, giving the little attention they need when it is required, carrying our bees through to the time when flowers give though be uptiful supply of the less than a beautiful supp give them a bountiful supply of the best of all sweets; when they in return will reward us by filling our surplus boxes? How we shall care care for, and how and what we shall do for the bees I must leave for the convention to solve.

A general discussion followed.

The Convention will meet at Monroe Hall, on Tuesday, May 24, 1881. A general invitation is extended to all that are interested in the management of the apiary.

D. A. CIPPERLY, Sec.

The Eastern New York Bee-Keepers' Association will hold a Convention in the Court House at Schoharie, N. Y., May 10 and 11. All interested in bee-keeping are cordially invited to attend.

W. S. WARD, Sec., Fuller's Station, N. Y.

## THOMAS C. NEWMAN.

EDITOR AND PROPRIETOR.

CHICAGO, ILL., APRIL 27, 1881.

## Welcome, Spring! Come at Last.

Once more the robin's cheerful piping and the bluebird's merry song can be heard in the early morning, as the golden sunshine tips the hill-tops, and the hills and valleys are arraying themselves in their gorgeous robes of emerald green. Soon dandelions, maples and fruit trees of all kinds will be in bloom, closely followed by an abundance of white clover, the leaves which are already becoming very numerous; a little later will follow a heavy basswood bloom, and we now believe the goldenrods and other wild flowers will be equally plenty. We hope our bee-keeping friends are now prepared for a vigorous season's work; if not, they have no time to lose, and especially is this true of those who are obliged to re-stock anew. Bees cannot now be moved too soon. Those expecting bees from the South should have them shipped at once, before the hives are tilled with new honey to daub the bees; those about to purchase bees should do so at once, thereby securing the first swarms, which will soon be cast in the South. We think now is the best time to buy, as every indication points to much higher prices, as soon as bloom is well developed and the prospect for a heavy honey flow and a good market are verified.

@Quite often we receive a rather uncourteous letter because the Bee JOURNAL is discontinued when the time is out that has been paid for. We try to please all our subscribers, but it is not an easy task for us to determine who does and who does not want it so continued. So we must ask to be informed on the subject. The following letter is just received and is just the kind of a notice we wish all would send who desire to have it sent without intermission. We then put this mark. after the name on the wrapper label, and when so marked do not stop sending the JOURNAL until we receive an order from the subscriber to do so.

" Please continue my JOURNAL right along; if I do not send the money on the day it runs out I do not want you to stop if, for I want every number as soon as it is published. I will send you the money just as soon as I can make it convenient to go to the post office to get a money order.

W. C. W. C get a money order.

Now, if all who desire it so continued would drop us a postal card, or mention it when they are sending a remittance, it would save us much trouble and themselves the annovance of having the JOURNAL stopped.

With this number several hundreds of subscriptions expire, and we hope puts his loss at one-half, and those left all will renew at once or else send us notice by return mail if they desire its continued visits.

Lee's, 2 miles n.w. of Pecatonica, Winnebago county, Ills., on the 17th of May, 1881.

J. STEWART, Sec.

## Review of the Situation.

From the East Saginaw, Mich., papers we learn that Dr. L. C. Whiting has received reports from parties owning at the commencement of winter 1.359 colonies of bees. Of this number only 432 are now alive, and many of thes€ are weak—and the end is not yet.

showing the number of colonies last fall and the number lost:

Dr. L. C. Whiting 90	,"i(1

Of course we give the above table from the Herald, without vonehing for its correctness, and without the knowledge of the parties named except Dr. Whiting, who very kindly sent us the papers.

It will be seen that the Misses Wilkins, of Farwell, have been the most successful, losing but 2 colonies out of 50. These ladies are among the most intelligent and progressive bee-keepers -their honey is always very attractive, and it is a pleasure to know that they are so successful. On our Museum shelves is a single-comb box of beautiful honey from the apiary of these ladies. It has been there since 1877, and has never leaked a particle, but looks as enticing to-day as ever. It was purchased where they sold their crop, without their knowledge.

We make the following extract from a recent letter from D. D. Palmer, Mercer county, Ill. Mr. Palmer's neighborhood has heretofore been one of the most successful bee-keeping districts in S. W. Illinois. The initials given represent apiarists of the highest order of intelligence, and will be readily identified by persons familiar with the reports of the Western Illinois & Eastern Iowa Conventions:

1 had 240 colonies, none left; S. 180,
20 left; L. 50, 3 left; H. 60, 20 left; L.
800, but few if any left; C. 163, 8 left;
B. 56, 16 left; H. 10, 17 left; H. 15, 6 B. 36, 16 left; 11, 40, 44 axis, 11, 16, 16 left; K. 17,7 left; and so I might go on through the list. Those that are left are work and the end is not yet. The through the list. Those charges are weak, and the end is not yet. The words of Thomas Paine are applicable to us her-keepers, "These are the times that try men's souls.

James Heddon, Cass county, Mich., are very weak. G. M. Doolittle, New York, estimated his loss at 40 percent., The next meeting of the N. W. a total loss in his locality, and C. W. Illinois and S. W. Wisconsin Bee-Keepers' Association, will be held at H. W. Lee's, 2 miles n.w. of Pecutoniae W. and was not yet "out of the woods." Hartford, Wis., there are probably less

thinks not more than I colony in 10 has requires that all the minutiae should be survived around Cedar Rapids, Iowa. county, Wis., thought very few bees Good estimates the loss at nine-tenths in Northern Indiana.

Losses in Maryland, Pennsylvania, Ohio, Kentucky, Missouri, Kansas, and The Herald gives the following table all States north of this line will prove unprecedentedly heavy. Those left are orous summer campaign.

It will be observed by a study of the department from week to week, that no Northern locality has been exempt from heavy loss, no manner of packing has been a guaranty of success, cellars have been more or less faulty, caves were transformed into charnel houses, cornstalks, straw and hav covered over them have failed to retain life, and the angel of gloom has found them as surely, and perhaps more quickly, where not prepared at all. Nor has any particular style of hive earned especial encomiums; the best approved frame hive has shared equally the odium with the log gam and box hive, and patented clap-traps have failed as life-insurance policies. The bees have to a great extent died, and no bee-keeper, however learned and scientific need blush to acknowledge that his bees, too, have been decimated by the long and unprecedentedly severe winter just passed.

We observe that at the late session of the Rock River Valley Convention, at the roll-call of colonies only 44 were reported living out of 207, 38 of which were brought through by Mr. Lucas without loss. We were requested to give "the cause of bees dving with plenty of stores, both in cellar and on summer stands" (see page 131). We must evade the question by the general answer, "The long, cold winter;" and yet, although an evasion, it is the only correct answer that can be given. During a mild or ordinary season, the requisites for successful wintering are not nearly so exacting as for a terribly severe and protracted season. A little defect in food is easily cured by one or two purifying flights in January: if all are old bees, the mid-winter thaw gives them a new lease of life, and the queen frequently takes advantage of it to deposit a few eggs; if the majority are new bees, a flight (which perhaps some have never had gives opportunity to change position, and invigorates them for that "masterly inactivity" so necessary to a prolonged life; if perchance the cluster has become divided, a broken winter gives opportunity for reuniting, and for diseased bees to become disengaged from the mass: if dampness pervade the hive (which is more or less the case in winter) it does but little if any harm so long as not congealed, but with extreme and protracted cold, it begins freezing at the outside, and chilling to the centre till it comes in contact with the bees, when they become benumbed, their physical organs cannot perform their functions, proper digestion ceases, and the bees die. The foregoing remarks are more or less applicable to all cases of out-door loss.

The losses in cellars and caves so prevalent the past winter are equally attrib- residence of W. B. Wallis, at Darlingntable to its length and severity.  $\Lambda$  ton, Wis., on Wednesday, May 11, 1881, than 100 left out of 462. T. B. Quinlan successful continement of 4 to 5 months, at 10 a.m.

very exact, and it is easy to imagine how Some weeks ago Mrs. Dunham, Brown the absence of the least requisite to success may become the principal factor in would survive in that district. I. R. producing death. Were it only the lesser bee-keepers or the novices who had suffered the heaviest losses, it might perhaps be attributed to ignorance or negligence in preparing them; but when we take into account the heavy losses by so many specialists and scientific beegenerally in very light condition, and keepers, we cannot but look upon such will require close attention and scien- a charge as an insult to intelligence. tific management to fit them for a vig- All the approved methods have equally proven failures.

We have been much interested in a mortuary reports published in our letter series of experiments being conducted by Mr. E. D. Godfrey, of Iowa, and would be pleased to hear from him the result of last winter, together with his method of preparation, and the general conclusions reached.

> But with the bee-keeper all is not lost, though he has lost all; with his hives and combs left, he still retains one-half or two thirds of his investment. The fruit-grower expects frequent failures in his crops, and is thankful that his trees survive without injury; the farmer's wheat winter-kills, when he plows up the ground in spring and plants anew in corn or something else, and replants if frost kills that; the stock-raiser who loses part of his flock, gives the remainder better attention, and patiently toils two or three years to repair his losses; the merchant has his seasons of loss, but with renewed push and activity makes up for the dull times when the "good time coming" has arrived; the stockbroker loses on his World-Belt Railway, projects a Short-Cut Line to the Moon, waters his stocks, and rides on the fleecy clouds of imagination to success; the speculator invests in anything possible, loses a part or all, compromises with his creditors, and with unconquerable zeal pushes on to success, a living monument to pluck; and the energetic bee-keeper, although many bright dreams may have vanished, will not despond, but without taking time to count the unteranted hives begins immediately to estimate the number he can refill. If the bees are all dead, he procures enough for a comfortable start, goes to work with a will to retrieve his losses, and while keeping time with the musical fram of his bees, in the "Sweet by-and-by" will reap a more than commensurate recompense for his vexations and disappoint-

> 188 Dr. N. P. Allen, President of the National Society, intends to be present at the Texas State Bee-Keepers' Association, at McKinney, Texas, on May 12 and 13, by invitation of Vice-President Collins. He is also invited by Vice-President Hipolite to spend a few days in the interest of bee-culture in Arkansas. He also intends to be present at the Missouri State Association if the time be fixed for the 1st week in June; being specially invited by Vice-President P. P. Collier. Dr. Allen starts on this trip during the first week in May, and we shall expect many items of interest from him concerning bee-culture in these States.

> The Southwestern Wisconsin Bee-Keepers' Association will meet at the

## MISCELLANEOUS.

Late Season in England.—In the London Journal of Hocticulture, Mr. Frank Cheshire says:

Few seasons would show more clearly the advantage of a special calendar than the present one. The lateness here is extreme, the temperature low, and the "weather forecast" not encouraging. In early springs, peach blossoms have been open on a south wall of ours on March I, but now, April 4, the tully swollen buds are yet waiting for a change before expanding. waiting for a

Buying Bees. The Indiana Farmer gives this good advice:

To those who contemplate buying bees we would say do so at once, buy now so as to take advantage of the season's work. If you cannot afford to buy full colonies, get good, strong nuoli, buy then early and they will grow, into good colonies during the season. It is best to buy as near home as possible as express charges are very high. Send to responsible dealers and stipulate that the bees must come early, so as to have advantage of all the increase of the season.

Feeding Bees in the Spring.-In the Prairie Farmer Mr. L. Harrison gives the following as her advice on this very important subject, at this season of the vear:

Naturalists teach us that insects during the larve state consume more food than they do during the remainder of their life. The queen bee is a wise and prudent mother, and counts the cost of their production, and governs her pro-ereative powers according to her in-come. She regulates her laying, not by the sealed stores in the hive, but by the amount brought in daily by her subjects.

If we wish to have our bees populous.

to profit by the early bloom, we must practice some strategy upon the "old lady," by which she is made to believe that the honey flow is continuous and abundant. Some bee-keepers recommend candy, of which sugar and flour of some kind are the principal ingredients. The objection to this kind of food is that bees must have water in order to manipulate it, and in order to procure it must leave the hive in inclement weather, and may get chilled and perin inclement ish. Thin uncapped honey is always found in the spring adjacent to the brood, and we should imitate nature as nearly as possible. Warm diluted honey, nearly as thin as it is when brought home from the flowers, and a substitute for pullon with respective. substitute for pollen, either in unbolted flour from wheat, rye or peas, should be supplied them in such a way that they would appropriate it to their use. There are many ways of feeding honey or syrup in vogue—such as a tumbler covered with muslin and inverted over the cluster, or a fruit can with perforations in the cover. It matters not how, so that the warmth of the hive is retained,

and that the bees feed readily from it.

We have two feeders on some of our hives, one containing thin honey and another with unbolted wheat flour, and although to-day, March 30, is windy with the thermometer at noon only 2 above freezing in the shade, the bees are rolling and tumbling in the flour, and working it into little balls upon their legs. In some localities it is an their legs. In some localities it is an advantage to feed flour, in sheltered nooks in the open air, but here it is different. The overflow from the river draws the frost from the roots of the elms and willows so that they are in bloom almost as soon as it is warm

# SELECTIONS FROM

Early Drones.—My 20 colonies of bees, put in the cellar Xov. 13, were taken out a few days ago, 16 living, and one of those much reduced, being in the cellar 147 days, in Langstroth frame hives, without division boards or cushinves, without division boards or enshions, and the same as they stood in the apiary in summer. This is the best result in wintering bees that I can hear of, in this county. B, lost 21 out of 24, cellar wintering; P, 13, all he had; and 4 other bee keepers, having 82 colonies, lost all margin of dynamics. lost all, mostly of dysentery. I have taken no pains to gather information as to the extent of the mortality of bees in this county, but what I hear is truly dis-couraging. Please tell me in the BEE JOURNAL why one of my colonies has plenty of drones flying, and the drones are associating with the other colonies; some colonies are killing them, while others are not molesting them. This colony had an Italian queen introduced has September, purchased from 1. S. Crowfoot, of Wisconsin.

H. I. BRICHENER.

Decorah, Iowa, April II, 1881.

The oneen is either an old one or physically deformed, so as to make of her what is termed a "drone-laying" queen, and in either case should be superseded.—Ed.]

All Gone.—On Nov. 12 I put 100 colonies in a cave. They had plenty of honey, all are dead but one; I packed 10 with chaff and corn fodder and they are all dead but one; leaving me 2 colonies out of 110. Mr. Brown had 200 colonies in a cave and all are dead but 5. Mr. Brown and I have put our bees in caves for 8 successive winters and in caves for 8 successive winters and have had success till this winter. Mr. Ward had 22 colonies in the cellar; all are dead. Mr. Wilson had 25 colonies in a dry cellar with plenty of honey, and all are dead. Mr. McAllister and Mrs. Kendall had 4 each in cellars and all have died. Mr. Cole had 9 left out of 14. There are others in this county but I have not heard from them yet. of 14. There are others in this country but I have not heard from them yet. I am well pleased with the Weekly BEE JOURNAL and would not do without it.

A. F. McKENRICH,

Camanche, Iowa, April 11, 1881.

Bees in Good Condition.-I had last fall 18 good colonies, and have 18 left now, all in good condition. They were They were wintered on the summer stands. confident 1 can winter bees as safe as other stock. S. H. HUTCHINSON, Mechanic Falls, Maine, April 10, 1881.

Lost 3 ont of 60 Colonies. - At least 65 think are dead; quite a number having a few colonies last fall have lost all; others having 20 to 40 colonies have others having 20 to 40 colonies have only 2 or 3 left. Of the few of our most successful—bee-keepers—are—Messrs. Hoffman, losing 35 out of 120; Drake, 10 out of 15; Clement, 60 out of 100, and Gans, 50 out of 100. Bees are wintered here mostly in cellars. I put 60 colonies on the 5th of Nov. in a bee house, lined and filled with a foot of sawdust, and up to the message by a lost only "colorible or the property of the colorible of the message by a lost only "colorible or the property of the colorible of the message by a lost only "colorible or the property of the colorible of the message by a lost only "colorible or the property of the colorible up to the present have lost only 3 colonies. I have all Italians, except one colony of Cyprians. I cannot do without the Bee Journal.

A. M. Wolcott.

Monroe, Wis., April 18, 1881.

Safely Wintered.—After a confinement of 160 days my bees are in excellent condition, considering the severe winter they have passed through, being the most severe we have had for 20 years. Last fall I had 32 colonies, all natives but one colony of hybrids. I prepared 13 of them with chaff cushions on top in Langstroth hives. The rest were box hives. They were put in the enough for bees to fly.

Plenty of sealed honey should be in the bive during the spring as a safeguard against starvation—a sort of lifeboat or contingent fund, to be drawn upon during an emergency, such as a cold storm.

On top in Langstroth hives. The rest were box hives. They were put in the cellar Nov. 30, and brought out April 9, all in a thriving condition with the exception of 4 colonies which I shall have to feed for a short time as they were late swarms. Many boxed according to the rest were box hives. They were put in the rest were box hives. They were put in the cellar Nov. 30, and brought out April 9, all in a thriving condition with the exception of 4 colonies which I shall have to feed for a short time as they were late swarms. Many boxed in the rest were box hives. They were put in the cellar Nov. 30, and brought out April 9, all in a thriving condition with the exception of 4 colonies which I shall have to feed for a short time as they were late swarms. Many boxed in the rest were box hives. They were put in the cellar Nov. 30, and brought out April 9, all in a thriving condition with the exception of 4 colonies which I shall have to feed for a short time as they were late swarms. to feed for a short time as they were late swarms. Many have lost heavily in this section. I find that all my neighbor bee-keepers and box hive men

who do not take a bee paper are the heaviest losers in bees. My bees were wintered at the Lake View Apiary, belonging to Mr. R. Squier, where there were 60 colonies and all came out alive, 1 did not think at first that 1 should like the Weekly as well as the Monthly, but since we have the news fresh every week I like it much better, coming as that of an old friend. just what we who are engaged in bee-culture need. Success to the Weekly BEE JOURNAL. J. G. A. WALLACE. Brighton, Outario, April 9, 1881.

Will Hogs Destroy Sweet Clover! Will Hogs Destroy Sweet Clover!— Royal jelly is young brood in the white state. In 1855 or 1856 I saw legs and breasts plainly in it in a colony prepar-ing to swarm which had no time to properly cut it up fine. I am satisfied that Rev. Mr. Mahin is right about bees and grapes. Birds are the main cause of damage tograpes. Will how destroy of damage to grapes. Will hogs destro sweet clover roots, if they are "running where they can get at them? LOUIS HOFSTATTER. Will hogs destroy

Louisville, Ky., April 1, 1881

(We do not know; but imagine that there is little about the tough, fibrous roots that even a hog would care to eat unless closely pastured upon it, and then would root it up only to keep busy.

Colonies Good and Strong.—I put 10 colonies in the cellar last fall and although they have had but one flight since October until March 5, they have since October until March 2, they have come out good, and strong in numbers, but some a little short of stores. About 6 bee-keepers around here report 18 to 12 dead. I like the BEE JOURNAL very uch. Samuel Sanderson. Elmira, Ont., April 18, 1881.

Expects a Fair Crop of Honey. -- My Expects a Fair Crop of Honey.—My 400 colonies were put into cellars early last November, and are there still, mostly in good condition. If the weather is sufficiently warm so that they can be taken out soon, my loss will not exceed 10 per cent. I attribute my success mostly to the excellent condition my bees were in last fall, and to the cellars in which they were wintered. There are a few others here that can give reports equally good, but not can give reports equally good, but not many. There were perhaps 3,000 colonies in this county last fall, and from all accounts there will be less than 1,000 left this spring. The loss is something all accounts there will be less than 1,000 left this spring. The loss is something imprecedented here. Nearly all our small bee-keepers have lost all they had. I have spoken with a number that had from 25 to 100 colonies, and their loss is fully 75 per cent. Farmers generally have lost all, owing to the insufficient care given them. Possibly the problem how to winter bees successfully will be solved by the experience of this winter. solved by the experience of this winter; if so, the loss will not be wholly without a gain. Appearances here are that the yield of honey will be fair in spite of greatly reduced number of laborers. White clover and basswood, our chief honey sources, are very promising. Jefferson, Wis.—George Grimm.

Fresh Air in Cellars Necessary,—The bees in my cellar, described in the JOURNAL, page 25, came through without the loss of a single colony, and all are in excellent condition. Another cellar that was not as well ventilated, but the half as to the first but the single colony. and that had no stone floor did not winter as well, one died and several were weak. This proves to my satisfaction that fresh air and plenty of it is what bees want to winter well. I shall pre-pare all my cellars like the one described in the JOURNAL before another winter. The thermometer in this did not vary 3 l winter. E. A. Thomas. Coleraine, Mass., April 16, 1881. all winter.

All Right.—I took my bees from the cellar on April 16, after 5 months' confinement, and from 41 colonies and 3 nuclei I have saved 38, all strong except 2 that are queenless, which I shall double up with 2 that are rather weak. I am cleaning them up and feeding them granulated sugar and rve-flour. Bees grammated sugar and Tye-nour. Loes are scarce in this vicinity: many bee-keepers have lost all. I wish the Jour-NAL great success. T. LASHBROOK, Waverly, Iowa, April 18, 1881,

Loss from 80 to 100 Per Cent.-Fully  $rac{7}{8}$  of the bees in this country which could fly last fall will never do so any more, and as a consequence beeswax will be cheap. The old togy bee-keepers who knew so much last fall have now very little to say about bees. I heard one say a few days ago that he thought that the honey had soured in the hives and killed the bees. I think he was a little sour on the bee question, too. I have lost about 80 per cent, of mine, others report a loss of 23 out of 25, some 100 per cent., and one of the most noted bee-keepers has lost 100 out of 138 (he is reported to have gathered and sold ten reported to have gathered and some con-tons of honey from his bees last fall), so you see that he understood the busi-ness, but did not save his bees. Those you see that he understoon the business, but did not save his bees. Those that I saved had dry goods boxes turned upside down over the hives, and were packed between with straw in advised to the control of the contro dition to the chaff in the hives. Scientific bee-keeping will stand a better chance now, for most of the box hive men have given up the business. Bees about here will have better care hereafter I hope. With renewed interest in bee-culture, I wish the BEE JOURNAL success.

GEO. M. LAWRENCE. Warsaw, N. Y., April 18, 1881.

Good Prospects.-Bees gathered the first pollen this season on the 14th inst., from the elm. Brood rearing is pro-gressing nicely. The white clover is from the elm. Brood rearing is progressing nicely. The white clover is green and growing. It is thick, and we have good prospects for a good honey season.

J. P. Moore.

Morgan, Ky., April 19, 1881.

Button Willow.—1 send you some cut-tings of a shrub that beats anything for tings of a shrub that bears any pollen for bees that I ever saw. If stuck pollen for bees that I ever saw, if stuck pollen for bees that I ever saw. in some damp ground they will grow just like willow-cuttings. Please give name. Spring is one worth behind D. A. PIKE. me. D. A. Ph Smithsburg, Md., April 18, 1881.

[The shrub is commonly known as button willow, and belongs to the numerous willow family. It grows quite plentiful in the Central and Western States, and is worthy of cultivation as well for its beauty as its enormous pollen yield.—Ed.]

Mortality of Bees in Iowa.—1 put 60 colonies in the cellar last fall, and have to-day taken out and examined them; there are only 25 alive, and some of them very weak. In this locality there is not over I colony in 10 left; some have lost all. I understand that Mr. W. II. Furman has only 7 or 8 left out of 60; another man lost 40, all he had. This is a This poor prospect for supply dealers. I like the Weekly BEE JOURNAL very much. Thos. B. QUINLAN, Cedar Rapids, Iowa, April 15, 1881.

Bees in Good Condition.-I menced the last season with 8 colonies. new I have 9 in good condition (having sold one I have only 8 to commence the season with.) My bees gathered some pollen this afternoon, the first this season.

Jos. II. FISHER.

Napoleon, O., April 18, 1881.

Wintered Well.—After 20 weeks confinement in the cellar I have taken my bees out, and find 5 dead out of 146. I put the hives close together in tiers, one bove another, 2x3 scantling between My bees are as strong and healthy a ever knew them to be in the spring. like the Weekly very much.

A. JENNINGS. Medusa, N. Y., April 18, 1881.

Overstocked With Bees,-Last fall I reduced my colonies about 40, leaving 75, which wintered without loss. My greatest trouble is to prevent increase. As there is no sale for bees here I an certainly overstocked. C. WEEKS. Clifton, Tenn., April 7, 1881.

Lost None.—I put my 111 colonies in the cellar last November and took them ont March 28. A few had the dysentery but I have lost none yet. I took them out a little too soon for it has been cold ever since, but they are doing well. Few bees are left here. O. C. BLANCHARD.

Ironton, Wis., April 20, 1881. Bee Locations and Hives.—This county is thickly settled; we have plenty of bloom of all kinds, and a running stream of water within 100 yards of my apiary; white and red clovers are abundant, and bees are few near here. Is this a good location for bees?

2. Which kind of hive do you prefer?
3. I am a carpenter and can make my own hives—are there any patents to hin-

der me from making a good hive?

4. Will it hurt to let bees fly when snow is on the ground? I like the BEE JOURNAL very much.

Cambridge City, Ind.

[1. With plenty of bloom (which implies summer and fall flowers are abundant), a running stream of water (which in Indiana is generally an indication of basswood), and an abundance of white and red clovers, we cannot possibly imagine the absence of anything but plenty of bees to make it one of the very best locations.

2. We prefer the standard Langstroth. Many very successful and scientific apiarists, however, prefer a shorter and deeper frame, while some want a much longer and deeper one.

3. There is no patent in the way of making any of the standard hives-Langstroth, American, Gallup, or Simplicity. With any of these, managed promptly and scientifically during a good honey flow, results will be satisfactory; but all the patented clap-traps in the world will fail to secure a honey yield, when the bees return to the hive without having found any.

4. No: a few may be lost in the snow. but when bees are needing a flight badly, and have commenced soiling the combs, it is frequently profitable economy to sacrifice a few to save the many.-ED.]

It Beats All .- The last season seems to be the worst one yet in the bee line. The causes here seem to have been a short crop of honey, then winter coming so suddenly, before scarcely anyone was prepared either in feeding or packwas prepared either in recening or packing, and lastly the long confinement. But according to all reports the best are in the same boat. I hope this year will turn up the sure method for wintering.

A. G. WOODBURY.

Winter Still Here.—My locality is, I think, as good for surplus honey as any part of Iowa. There is an abundance of linden timber all around here. I have saved some expressly for my bees. In November I put them on the south side of a tight board fence, about one foot apart. I packed straw all around exapart. I packed straw all around except in front, filled the surplus boxes with dry oak leaves and then covered them with slough grass. I have 15 colonies left out of 25. In Warren county % of the bees are dead that were wintered out-of-doors; those in the cellars are there yet. We expected warm weather but this morning finds there are 10 inches of show on the ground. are 10 inches of snow on the ground. I like the Weekly JOURNAL and I would not like to do without it.

HIBERT CLARK.

Palmyra, Iowa, April 8, 1881.

Good-Bye March. — The month of March has come and gone and I earnestly hope we may never see another like it. It came in like a lion, continued like a lion, and went out like a whole cage of lions fighting and howling. It has been one continued cold alligned all through with but Love ing. It has been one continued cold blizzard all through with but 1 or 2 warm days in it. I say again, "hurrah for chaff packing on summer stands;" although winter set in early, continued severe and remained late, still I have mot lost a colony and have only one weak, and that was wintered in an observatory hive and did well until March 15 when I found the glass sides were covered with ice and bees were being chilled as it melted. I therefore united them with another. If this month comes out warm I shall not lose any more find a large amount of brood and hatching bees in all my hives, some having 5 frames well filled. This is due, I think,

to strong colonies and packing on summer stands with plenty of honey. Many bees in this locality were packed on their summer stands but were not put in proper condition; many were packed after winter set in and seemed to die first, late packing causing them to fill with honey, and having no fly, afterwards took the dysentery; several I have examined which died with good packing, bees and honey dry, and emit-ling a sweet odor; these I learned ceased breeding in September, but were strong in old bees. I have found were strong in old bees. I have found none starved. The honey yield last fall gave them a chance to fill up well. All withstood the severe weather of winter and were in good strong condition March 1, but died during the month. If all had had one frame of brood Oct. 15, they would have had bees to rear brood in February, which would have saved them. I gave several of my colonies a frame of brood from other hives Oct. 15, which saved them. think. I look eagerly each week for the Journal and follow its teachings.

E. A. Morgan.

Arcadia, Wis., March 31, 1881.

Plan of Wintering Fails.-A thaw the last week of March gave our bees a flight, and the bee-keeper a chance to look them over and see "what of life there yet remained." One-half of of life there yet remained." One-half of my colonies were then dead and of those left many were weak and by the time spring comes (if it ever does) there will not be over  $\frac{1}{3}$  left. It is cold and snowy yet, not a bud is swelling on anything: no farm work is done, and gloom rests over hill and valley. Most of the bees in this vicinity are dead. Three report a total loss; 2 have lost 4-5; another had 18 left out of 83. Myself and another have 2-5 living. I wintered on the summer stands without protection. Every method of packing was used by Every method of packing was used by the apiarists referred to, while all used the same kind of hives, and those un-protected have done as well as those packed on the most approved plan.
WM. Morris.

Anderson, Iowa, April 12, 1881.

Swarming.—I have no difficulty in wintering, and even in getting lots of honey; but the swarming propensity I cannot control satisfactorily. Please give information in the Journal. E. Gloucester, Mass. A. Parsons.

[The swarming propensity can generally be checked by removing 3 or 4 frames of sealed brood to some weak colony, putting empty combs or foundation in their place, and destroying all queen cells. Sometimes it can only be controlled by transposing a weak colony in place of the strong one. Should they still persist, then divide, removing the queen and leaving a ripe cell.-ED.]

The Survival of the Fittest .- In the early part of November I put away 31 colonies with blankets on the frames, packed prairie hay around the hives and filled the caps; they were protected by a tight board fence on the north and by a tight board rence on the north and west—all south exposures; tops were protected from rain and snow; 24 others were in American hives and 7 in Langstroth. I am feeding the weak and giving them all the rye-meal they will take. We have had fearful weather—we petural pollen yet. I expect to —no natural pollen yet. I expect to transfer all my bees from the Ameritransfer all my bees from the American to Langstroth hives during the season, if possible. Nearly all the bees in this vicinity are dead; I might say at least 4-5 of them, yet under the law of the "survival of the fittest" we may expect our race to improve at least in endurance. The different theories about loss of bees are amusing to a about loss of bees are anusing to a novice; what is one man's meat is another's poison—there seems to be "death in the pot" from all quarters. I give my results for all they are worth, without comment. Out of 31 I have lost so far 7: expect to lose about \(^1\_3\) or nearly so. I am glad to do so well, when I look around and find death written everyaround and and death writen everywhere. I like the change in the paper as it brings us information which in the Monthly would be too late to be of value to us.

F. A. GROVE. Kirksville, Mo., April 13, 1881,

Seven From One Colony. - I commenced last season with one colony, and as increase was my object I bought and as increase was my object I bought a lot of empty combs in Langstroth frames, fed sugar-syrup and stimulated breeding, and by dividing made 7 colonies from one. I wintered in chaff hives; after 68 days confinement they had a good flight, and are now all in good condition with brood in all stages. Of the bees in this county 23 are dead. Put me down for a life subscriber for the Bee Journal. J. F. Kight. Poseyville, Ind., March 21, 1881. the BEE JOURNAL. J. F. Kigs Poseyville, Ind., March 21, 1881.

Conventions. - I was much pleased with Mr. Heddon's observations on conventions. He is right. What we want is talk and discussion, not longwinded essays and speeches. Let me suggest that the subjects be made up and published, and then let the memduestion in a short, terse manner, remembering that Casar sent home the report of a whole campaign in 3 words. Let me give a sample—subject: Laying Worker.—I took from it all the combs without the bees, distributed them among strong colonies, replaced them with combs of brood and some bees from strong colonies, gave them a queen cell about to hatch, and in a few days all was lovely. Again: Dysentery.—
Made several new swarms, noticed they had the dysentery; examined and found they had no honey; gave them some and all was right again. I wonder if St. Joseph country belongs to the south-

west corner of Michigan.
E. B. SOUTHWICK.
Mendon, Mich., April 15, 1881.

Royal Jelly.—I see in the BEE JOURNAL of March 29, page 89, that Mr. C. J. Robinson takes the position that royal jelly is composed of honey, bee-bread and drones' semen, and that the semen of the drone is annually deposited in the combs, and affords a supply for queen-rearing after the destruction of the drones in the fall until their return the next season; also, that the semen the next season; also, that the semen in the royal jelly is the agent that im-pregnates the embryo ovary of the queen while in a larval state, and vivities myriads of egg germs so they will produce drones in the course of time. We are furnished with no method of ascertaining the truth of the assertion that a deposit of drone's semen is made in the combs. Can it be so, and how shall we find the truth? Now, 1 propose a test, by removing from a colony of bees all the combs of the previous season, and put the bees upon comb foundation and feed well, before any drones make their appearance. After the eggs hatch in the new combs, remove the queen and continue to feed honey and flour, and see what the result will be.

Camargo, Ill.

Ninety Per Cent. of Loss .- There has been a fearful loss of bees in this section. Some old bee-keepers have lost tion. Some old bee-keepers have lost as high as 90 per cent. I had last fall 20 colonies in the Shuck hive packed with chaff, and 8 colonies in single-walled hives with chaff cushions over the frames—all were on the summer stands. I lost 6 in the Shuck hives, and 6 in the single-walled, leaving 16 to begin the season with. I think the prospects are good for a plentiful boyer. of in the single-waited, leaving 16 to begin the season with. I think the prospects are good for a plentiful honey flow. I like the Weekly JOURNAL very much, but prefer the size and shape of the Monthly. C. W. HELLEMS. St. Catharines, Ont., April 11, 1881.

No Loss of Bees .- I am happily disappointed, for my bees have cothrough this long severe winter through through this long severe winter all right; they were confined in their hives from November until March, and I feared the result. I wintered on the summer stands in single-walled hives, packed with sorgum cane grindings, contracted the brood chamber on each side with division boards, placed cobs over the top boards of brood frames and then gunny sacks and old clothing. I have kept my bees mostly in the Dexter hive; it is like Root's simplicity, only more simple, and supplied with the American frame. I intend to transfer them into the "Fisk hive." This is a double-walled hive with dead air space between the walls, with a very slanting, self-cleaning, stationary bot-

tom board; it is a 2-story hive. The inside wall is both lathed and plastered, and contains 8 Langstroth frames. I am married to this last named hive as you see the name indicates, for I believe it is the best hive that can be produced, both for summering and wintering. I would like to see more in the bee-papers about plaster hives, lime absorbpers about plaster hives, lime absorbents, etc., for I take more to the lime idea than to chaff or sawdust. Honey bees fared poorly in this section last year; there was no surplus nor swarms and many have died this winter and spring, especially among the careless and uninitiated bee-keepers. I like the BEE JOURNAL very much, and so do those who subscribe here as far as I have heard from.

A. W. FISK.

Bushnell, Ill., April 18, 1881.

Bushnell, Ill., April 18, 1881.

Why The Bees Die.—About 80 per cent. of the bees in this vicinity are dead. The apparent causes of the mortality are: First, the 5 months of close confinement; 2d, severe and long continued cold weather; 3d, improperly constructed entrances stopped up by sleet, snow, and dead bees, causing smothering. I lost 2 out of 45 colonies from the 2d cause. O. Foster. O. Foster.

Mt. Vernon. Iowa.

Long Winter.—Bees in central Iowa are suffering greatly from long confinement and losses will be very heavy, more so than most of us are aware. Bees have been dead as to sunshine since the 20th of October, almost 6 months, and no signs for a flight for some time yet, as we have 6 inches of some time yet, as we have a liches of snow on the ground now and very cold nights. We may safely say that 34 the bees in this locality are dead. But I do not think I have lost very heavily Mat I yet. I never saw bees more quiet than mine are considering the length of time they have been up. But spring is a very bad time on bees here, we have so much cold wind in the spring; that of course results in spring dwindling and a great many bees are to go after farmers are satisfied that what bees they have left are all right.

Corplete Lorge April 1999. are all right. J. E. HAS' Carlisle, Iowa, April 14, 1881.

Palestine Bees More Hardy.—About 9-10 of the bees in northern Indiana are dead. I have lost 120 out of 170 colonies. I had in my apiary one queen imported from Palestine and about 50 young queens reared from her that have stood the winter well, although my Italian queens are nearly all dead. I think ian queens are nearly all dead. I think the Palestine bees will prove to be a very superior race in all respects.

Nappanee, Ind. I. R. Good.

Chins from Sweet Home.—Our advertisement in the American Bee Jour-nal has brought us more inquiries for our Sweet Home Raspberries all other papers we advertised in. I send you a sample of such honey as our bees have tried to winter on. It is honey dew, which I understand to mean the secretion of aphides which is neither honey nor dew. New Boston, Ill. D. D. PALMER.

Unward Ventilation.-My bees were wintered in the cellar, and those that had honey enough (though of a very poor quality) are all right. I was busy in the fall and thought they were gathin the fall and thought they were gathering enough honey to winter on, but when I came to carry them into their winter quarters I found, when too late, that they were light, and, the winter being extremely long, they starved to death. I do not think bees will ever die with the dysentery with plenty of good honey, a good, warm cellar, with plenty of upward ventilation; at least, that has been my experience for the last 15 years. My cellar is not a very dry one, but I never had the combs mold. I think that too little upward ventilation and poor honey have killed mold. I think that too incre upward ventilation and poor honey have killed the bees. Nearly all the bees in this vicinity are dead. I have but 45 colonies left out of 80 last fall.

Marley, Ill. FRANK SEARLES.

Loss 30 Per Cent.-Bees around here have suffered very severely; nearly all are dead. I have lost 30 per cent.

Iowa City, Iowa, April 15, 1881.

# SPECIAL NOTICES.

Single copies of the JOURNAL are sent postage paid for 5 cents each.

The attention of bee-keepers is directed to the advertisement of Champion Bee Hive Manufacturing Co.

Those who may wish to change from other editions to the Weekly, can do so by paying the difference.

The Volume of the BEE JOUR-NAL for 1880, bound in stiff paper covers, will be sent by mail, for \$1.50.

 $\hfill \begin{tabular}{ll} \hfill \$ 

We have prepared Ribbon Badges for bee-keepers, on which are printed a large bee in gold. Price 10 cents each, or \$8.00 per hundred.

Notices and advertisements intended for the Weekly BEE JOURNAL must reach this office by Friday of the

We can supply but a few more of the back numbers to new subscribers. If any want them, they must be sent for

Constitutions and By-Laws for local Associations \$2 per 100. The name of the Association printed in the blanks for 50 cents extra.

Grav Hairs Are Honorable but their premature appearance is annoying. Parker's Hair Balsam is popular for cleanliness and promptly restoring the youthful color.

The date following the name on the wrapper label of this paper indicates the time to which you have paid. In making remittances, always send by postal order, registered letter, or by draft on Chicago or New York. Drafts on other cities, and local checks, are not taken by the banks in this city except at a discount of 25c., to pay expense of collecting them.

PREMIUMS.—For a club of 2, weekly PREMIUMS.—For a club of 2, weekly we will give a copy of "Bee-Culture;" for a club of 5, weekly, we will give a copy of "Cook's Manual," bound in cloth; for a club of 6, we give a copy of the JOURNAL for a year free. Do not forget that it will pay to devote a few hours to the BEE JOURNAL.

😭 At the Chicago meeting of the National Society we were requested to get photographs of the leading apiarists, to photographs of the leading aparists, to sell to those who wanted them. We can now supply the following at 25 cents each: Dzierzon, the Baron of Berlepsch, and Langstroth. The likeness of Mr.Langstroth we have copied, is one furnished by his daughter, who says, "it is the only one ever taken when he was in good health and spirits." We are glad to be able to secure one of such a satisfactory nature. a satisfactory nature.

BEE JOURNAL will be sent free to any names that may be sent in. Any one intending to get up a club can have sample copies sent to the persons they desire to interview, by sending the names to this office. names to this office.

It would save us much trouble, if all would be particular to give their P.O. address and name, when writing to this office. We have several letters (some inclosing money) that have no name. Many others having no Postoffice, County or State. Also, if you live near one postoffice and get your man at another, be sure to give the address we have on our list.

# Books for Bee-Keepers.

Cook's Manual of the Aplary.—Entirely re-written, greatly enlarged and elegantly illustrated, and is fully me with the times on every conceivable subject that interests the uplarist. It is not only in-structive, but intensely interesting and thoroughly practical. The book is a masterly production, and one that no bee-keeper, however limited his means, can afford to do without. Cloth \$1.25; paper, \$1.

Quinby's New Bee-Keeping, by L. C. Root.— The author has treated the subject of bee keeping in a manner that cannot fail to interest all. Its style is plain and forcible, anaking all its readers sensible that the author is master of the subject.—\$1.50.

Novice's A B C of Rec-Culture, by A. I. Root.
This emitraces "everything pertaining to the care of
the honey-bee," and is valuable to beginners and
those more advanced. Cloth, \$1.25; paper, \$1.00.
King." Mee-Keepers' Text-Book, by A. J.
King. "his edition is revised and brought down to
the present time. Cloth, \$1.00; paper, 75c.

Langstroth on the Hive and Honey Ree This is a standard scientific work. Price, \$2.00.

Langstroin in the Hive and Honey lice
This is a standard scientific work. Price, 82.00.

Hiessed Mees, by John Allen.—A romance of
bee-keeping, full of practical information and contagions enthusiasm. Cloth, \$1.00.

Hee-Culture; or Successful Management
of the Aplary, by Thomas G. Newman.—This
pamphlet embraces the following subjects: The Location of the Aplary.—Honey Plants—Queen Rearing
—Feeding—Swarming—Dividing—Transferring-Italianizing—latroducing gueens—Extracting—Quieting
and Handling Bees—The Newest Method of Preparing Honey for Market, etc. It is published in English and German.—Price for either edition, 40
cents, postpaid, or \$3.00 per dozen.

Food Adulteration; What we eat and should
not eat. This book should be in every family, where
it ought to create a sentiment against the adulteration of food products, and demand a law to protect
consumers against the many health-destroying adulterations offered as food. 200 pages. Paper, 50c.

The Uzlerzon Theory;—presents the fandamontal principles of beaceuties.

consumers against the many health-destroying adulterations offered as food. 200 pages. Paper, 50c.

The Dzierzon Theory;—presents the fandamental principles of bee-culture, and furnishes a condensed statement of the facts and arguments by which they are demonstrated. Price, 15 cents.

Honey, as Food and Medicine, by Thomas G. Newman.—This is a pamphlet of 24 pages, discoursing upon the Ancient History of Bees and Honey, the nature, quality, sources, and preparation of Honey the nature, quality, sources, and preparation of Honey for the Market; Honey as an article of food, giving recipes for making Honey Cakes, Cookies, Paddings, Foam, Wines, &c.; and Honey as Medicine, followed by many useful Recipes. It is intended for consumers, and should be scattered by thousands all over the country, and thus usus it in creating a demand for honey. Published in English and German. Price for either edition, 6c.; per dozen, 50c.

Wintering Bees.—This pamphlet contains all the Prize Essays on this important subject, that were read before the Centennial Bee-Keepers' Association. The Prize-425 in gold—was awarded to Prof. Cook's Essay, which is given in full. Price, 10c.

The Hive I Une—Being a description of the hive used by G. M. Doolittle. Price, 5c.

used by G. M. Doolittle. Price, 5c.

Extracted Honey; Harvesting, Handling and Marketing. A 24-page pamphlet, by Ch. & C. P. Dadant, Hamilton, III. This gives in detail the methods and management adopted in their apiary. It contains many useful hints.—Price 15c.

It contains many useful limits.—Price 13c.

Princtleal Hints to Bee-Keepers, by Chas. F.

Mith; 32 pages. It gives Mr. Math's views on the
management of bees, Price, IOc.

Kendnil's Horse Brok.—No book can be more
